INDEX TO ILLUSTRATIONS

- cacia* Balleyana, 249; *leprosa* 245; *verticillata*, 665.
Acorus Calamus variegatus, 139.
Ethionema amomum, 368; *pulchellum*, 368.
Agapanthus Mooreanus, 98.
Ailanthus Vilmoriniana, 574.
 Alpine house at Oxted Place, 468.
Alstromeria aurantiaca, 431.
Alstromeria, a border of, 404.
Anagallis Monelli Willmoreana, 478.
Anchusa italica Dromore Variety, 1, 577.
Androsace laeta, 492; *linguosa* *oculata*, 203; *longifolia*?, 263; *sarmentosa*, 254.
Anemone alpina, 201; *japonica*, 348; *pinnatifida*, 249; *St. Brigid*, 4; *Crowley's White*, 309.
Anemones, *St. Brigid*, 474.
Anthyllis Hermannia, 371.
Antirrhinum, border of, 6.
Ant, nest, 153.
Aponogon distachyon, 261.
 Apple John Waterer, 521.
 Apples attacked by the Codling Moth, 516.
Aquilegia alpina vera, 69; *glandulosa*, 316.
Arabis auriculoides, 184.
Arbutus *Andrachne*, 92; *Menziesii*, 471; *Unedo*, 490.
Arctostaphylos Manzanita, 122, 231; *Uva-Ursi myrtifolia*, 206.
Aristolochia gigantea, 398.
Artemisia lactiflora, 40.
Arteris acris, 499; *Pioneer*, 619; *Queen of Colwall*, 617.
Aubrietia on a wall, 254.
Azalea, a typical *Cherry*, 552; a typical *Kumme*, 562; *Daviesii*, 617.
Azaleas in woodland, 618.
Bambusa pumila, 322.
 Barberries under frost, 3.
 Bean, Broad, the new "Sutton," 22.
Begonia Eunice, 260; *Gloire de Lorraine*, 637; *Hilda Langdon*, 55, 258; *Venus*, 55.
Berberis brachypoda Gibbsii, 554; *Comet*, 578; *Darwinii*, 232; *japonica*, 574; *replicata*, 186; *stenophylla*, 4, 92; *Tom Thumb*, 555.
 Border, a herbaceous, 588.
Bougainvillea glabra, 582.
Buddleia alternifolia, 52; *auriculata*, 579; *Colvillei*, 366; *Golden Glow*, 679; *Moonlight*, 526; *variabilis*, 116.
Bupthalmum speciosum, 383.
Cabbage, pests of the, 680.
Calceolaria polycoriza, 626.
Callistemon salignus, 454.
Callunas, 79.
Calochortus Maeanus, 474.
Calycos borealis, 305.
Camellia Jupiter, 44; *Snowflake*, 70.
Campanula Allionii, 400; *calicifolia*, 294; *Halli*, 427; *persicifolia*, 19; *Byrburgh*, 370; *Portenschlagiana*, 12; *pumila*, 411; *Spetchley*, 372; *Zoysii*, 411.
Carnation, border, *Jessie Murray*, 675; *King of Cloves*, 675; *Viceroy*, 119.
Carnation, Perpetual Flowering, *Amos Grove*, 258; *Chintz*, 426; *Donald*, 296; *Scarlet Iona*, 296; *Surprise*, 296.
Carpenteria californica, 91, 444.
 Carrot New Intermediate, 20.
Carya porcina, 462.
Castanea sativa, 455.
Ceanothus thyrsiflorus, 486, 632.
Centaurea montana, 24.
Centipedes, 664.
Cerasus Lannesiana var. *Botanica*, 262; *pendula*, 498.
Chelsea, Allwood's *Carnations* and *Allwoodii* at, 288; *Bunyard's Iris* garden at, 277; *Carters' spring garden* at, 290; *Cherry's garden* at, 290; *Clarence Elliott's alpine meadow* at, 271; *Dr. Macwatt's Primulas* at, 481; *Ernest Dixon's garden* at, 273; *Gaze's informal garden* at, 273; *MacDonald's Grasses* at, 275; *Orpington Nurseries Polyantha* *Roses* at, 275; *Perry's Ferns* at, 276; *Sutton's annuals* at, 278; *Symons-Jenne's rock garden* at, 272; *Tucker's rock garden* at, 291; *Wallace's Lilies* at, 274.
Chelsea, Whitelegg's *Iris* at, 277; *Whitelegg's rock garden* at, 271.
Chimaphila maculata, 432.
Chimonanthus fragrans, 26.
Choisya ternata a hedge of, 83.
Chrysanthemum Brightness, 663; *Miss Joyce Moore*, 608; *Norman Davis*, 581; *Pink Beauty*, 608; *Snow Queen*, 627.
Chrysanthemum, Japanese Mountain, 56; sections of typical Single, 610.
Cimicifuga japonica, 563; *simplex*, 563.
Cineraria, a typical florist's, 162; *Feltham Beauty*, 162; *Forget-me-not Blue*, 120.
Cistus crispus, 303.
Cladrastis sinensis, 399.
Clematis, a, from seed, 611; *Armandi*, 631; *Flammula*, 297; *florida*, 340; *Jackmanni*, 328; *Lady Londesborough*, 486; *macropetala*, 227; *montana*, 340; *montana rubens*, 339, 632; *Nellie Moser*, 196; *Perle d'Azur*, 327; *The Bude*, 328; *Thunbergii*, 598.
Clethra punicea, 331.
Clethra, 148.
Cloches, use of, 25.
Codonopsis ovata, 124.
Convolvulus major, 68.
Cordylina australis, 47, 575.
Cosmea, Sutton's *Early Double*, 57.
Cotoneaster buxifolia, 28; *Danmeri radicans*, 27; *frigida*, 28; *horizontalis*, 28; *salicifolia rugosa*, 42; *Simonsii*, 42.
Cranbourne Court, garden at, 164.
Crataegus cordata, 461; *stipulacea*, 462.
Crocus Cloth of Silver, 125; *E. A. Bowles*, 197; *longiflorus*, 500; *Sieberti versicolor*, 168; *speciosus*, 550; *speciosus albus*, 549; *vernus*, 201, 524.
Crocus, 58; among *Grass*, 77; by the pathside, 78.
Curant, Daniel's *September Black*, 504.
Cyclamen, *Comet*, 448; *Firefly*, 45; *Giant White*, 501; *hyemale*, 8; *Mrs. Buckton*, 500; *neapolitanum*, 447; *pseud-ibericum*, 448; *repandum album*, 448.
Cyclamens, hardy, in woodland, 618; in moraine, 557.
Cynoglossum linifolium, 335.
Cypripedium montanum, 315.
Cytisus Ardoini, 643; *Kewensis*, 93; *præcox*, 116; *scoparius sulphureus*, 281.
Daboecia polifolia, 342, 401.
Daffodil, a fasciated, 229; *Beersheba*, 211, 262; *Bernardino*, 409; *Everest*, 73; *Jessie*, 225; *Miss Helen O'Hara*, 212; *Opera*, 225; *Puritan Maiden*, 198; *Victoria*, fasciated, 250; *Silver Rupee*, 234; *Sollart*, 234.
Daffodils, at *Warley*, 130; *Trumpet*, 130.
Dahlia, a new type of *Paeony*-flowered, 54; *Dorking Star*, 511; *Gloria*, 491; *Kitty*, 530; *Little Jennie*, 479; *Mrs. E. G. Cant*, 491; *Rossella Amos*, 54; *Sweet*, 555; *Vive La France*, 505.
Daphne Cneorum, 255; *petraea*, 255.
Daphnium, a fine white seedling, 151; *Blue Boy*, 346; *Chimex*, 464; *My Lady*, 371; *Unique*, 346.
Dianthus callizonus, 46.
Dianthus Herbertii Bridesmaid, 489; *Fire King*, 489; *May Queen*, 106; *Model*, 289; *Mrs. Giffard Woolley*, 398; *Red Indian*, 59.
Dicentra Fraxinella, 238.
Dimorphotheca aurantiaca, 270.
Dodecatheon radicans, 287.
Douglasia hevigata, 237.
Draba Aizoon, 657; *Dedeana*, 538; *pyrenaica*, 658; *rigida*, 658.
Drosera spatulata, 183.
Dryas octopetala, 69, 292.
Earwig, the 613.
Eriogonum japonicum, 607.
Eriophris Elwesiana, 296.
Eriobotrya japonica, 374.
Erica arborea, 677; *vagans alba*, 488; *Veitchii*, 222.
Erigeron micranthus, 474.
Erinus alpinus, 279.
Eritrichium nanum, 2.
Erodium chelidanthoidum, 330; *coriandrum*, 330.
Erythrina Crista-Galli, 453.
Erythronium californicum, 137; *revolutum*, 135.
Escallonia Donald Seedling, 407.
Enonids punctata, 517.
"Everyman's" patent straining wire, 548.
Fabiana imbricata, 321.
Fatsia japonica, 48.
Ferns growing in bottles, 61.
Foxglove, the stately, 373.
Foxgloves from seed, 470.
Freesia Canary, 113.
Freesias, 169; coloured, 367.
Fritillaria Melegriis, 317, 422.
 Fruit trees, protecting, 284.
Galanthus Imperati, 72.
 Garden, an Essex, 594.
 Garden design: plan for a semi-garden, 676; plan of town garden, 123; plans, 66; plan for a herbaceous walk, 622; plan showing formal and informal planting, 544; planting plan for a shrubby glade, 595.
 Garden ornament, a, 82.
Garrya elliptica, 382; *dalmatica*, 620; *hispanica*, 621; *horrida*, 629; *pilosa*, 562.
Gemma japonica, 540; *Farreri*, 457, 493; *Freydiana*, 16; *Gentianella*, 15, 241, 444; *Lago-derchiana*, 16; *sino-ornata*, 16, 545.
Geranium anemonifolium, 188; *cinereum album*, 313; *lancastriense*, 314; *Pyrolanum*, 181.
Gladiolus Darling, 466; *Incon- testable*, 426; *Linton*, 429; *Nightingale*, 465; *Nydia*, 380; *Odin*, 370; *Salmon Beauty*, 480; *Unpassable*, 103; *Utopia*, 329; *Zanthia*, 465; *Zenobia*, 429.
Gloxinia, a typical modern, 33.
Gooseberry *Sawfly*, the, 418.
Grape Apple *Towers*, 32.
Grapes, a pot of *Muscata*, 334.
Hamamelis japonica, 661; *japonica arborea*, 660; *modis*, 52, 660.
 Heath garden, at *Gravetye*, 222.
 Heaths at *Brockhurst*, 205; in the rock garden, 157.
Hedychium, 422.
Helleborus at *Manstead Wood*, 136.
Helleborus corsicus, 644; *niger* among *Ferns*, 9.
Hemerocallis lara, 646.
 Herbaceous walk at *Cranbourne Court*, 623.
 Holland Park Hall, *Bunyard's Apples* at, 527; *Hon. Vicary Gibbs' Vegetables* at, 527; *MacDonald's Grass* exhibit at, 529.
Hollyhocks, 174.
Houttuynia cordata, 674.
Hyacinths at *Haarlem Show*, 71; *blue*, 44; *Messrs. Sutton's*, 148; *Propagation* of, 10.
Hyacinthus azureus, 168.
Hydrangea hortensis Martiesii, 431; *paniculata grandiflora*, 40.
Hymenanthera crassifolia, 566.
Hypericum calycinum, 458.
Ilex Aquifolium argentea marginata, 18; *A. tricolor-luteo*, 439; *A. pendula*, 17; *verticillata*, 640.
Iris Aphrodite, 359; *Artemis*, 473; *Bertrand*, 358; *Black Prince*, 375; *Douglasiana Norton*, 246; *Kämpferi*, 143; *Geisha*, 144; *Morning Mists*, 144; *Starry Heavens*, 144; *Kashimiriana*, 356; *Lady Lilford*, fasciated bloom of, 350; *hevigata alba*, 144; *Monsieur*, 355; *Mrs. J. Stern*, 358; *reticulata*, 75; *sibirica*, 357; *tenax purpurea*, 246; *Thundercloud*, 319; *variegata*, 475; *xiphoides*, 381.
Iris, Bearded, 353, 354; *Bearded*, by the pathside, 354; the "Rothschilds," 438.
Jasminum primulinum, 195.
Kniphofia *comosa*, 510; *comosa*, showing curious method of flowering, 583; *erecta*, 509; *multiflora*, 161; *Rouge et Soufre*, 161; *rufa*, 510.
Kniphofia Tysoni, 519.
Kolkwitzia amabilis, 347.
Lachenalia Nelsoni, 197.
Laurus exaltis, 637.
Lathraea Clavellata, 108.
Lavender Walk at *Oxted Place*, 653; at *Warley Place*, 92.
Leptophyllum buxifolium, 243.
Leptospermum scoparium *Nymen's* var., 343.
Leucocymum aestivum, 280, 467; *nigrescens*, 60; *vernum carpatum*, 74.
Ligustrum Quibon, 526.
Lilac Marie Legraye, 302; *Princess Clementine*, 302.
Lilacs at *Kew*, 301.
Lilium auratum, 35; *auratum platyphyllum*, 449; *candidum*, 39, 412; *centifolium*, 118; *gigantum*, 213; *Henryi*, 102; *Martagon album*, 394, 441; *monadelphum Szovitzianum*, 413; *Mrs. R. O. Backhouse*, 440; *Parryi*, 102; *philippinense formosanum* *Prie's* variety, 118; *regale*, 101, 450, 546; *Sargentii*, 394; *testaceum*, 393; *Willmottii*, 101.
Lily pool, a reader's, 569.
Linaria alpina, 633; *Cymbalaria*, 634.
Lithospermum intermedium, 2; *prostratum*, 314.
Linaria rediviva, 309.
Lupinus in the border, 105; three typical, 105.
Lupinus Light of Loddon, 333.
Magnolia glauca, 366; *Lennel*, 263.
Malvastrum campanulatum, 182.
Martynia proboscidea, 445.
Meconopsis chelidoniifolia, 170; *heterophylla*, 171; *lancifolia*, 293; *latifolia*, 170; *racemosa*, 170.
Menyanthes trifoliata, 80.
Millipedes, 664.
Minulus Bartonianus, 362.
Montbretia Jessie, 504.
Mont Cenis Lake, 648.
Morae iridoides, 403.
Morisia hypogaea, 228.
 Moth, the *Codling*, 516; the *Diamond-Back*, 432.
Musa japonica at *Oxted*, 518.
Myosotis Roll of Honour, 2.
Narcissi, large-flowered paper-white, 395; *Star*, 130.
Narcissus, a proliferous (book plate), 323; *Beersheba*, 262; *Bulbocodium citrinus*, 167; *Glorious*, 172; *Golden Empress*, 149; *Golden Herald*, 121; *Great Dane*, 149; *Iris*, 240; *Johnsoni*, 168; *Mrs. R. O. Backhouse*, 160; *pallidus præcox*, 525; *Pheasant's Eye*, in Switzerland, 137; *trianthus*, hybrid seedlings of, 187; *Tri- mon*, 129; *Umbria*, 173.
 National Chrysanthemum Society's Show, *Cole's* exhibit at, 580; *Luxford's* exhibit at, 580.
Nephrolepis exaltata, 23.
Nerine Bowdini, 612.
Nerium Oleander, 427.
Nicotiana alata, 43.
Nymphaea stellata, 117.
Nymphæas at *Market Bosworth*, 534.
Oenothera biennis, 507.
Olearia macrodonta, 365.
Olympia, gardens at, *Messrs. Carters*, 134; *Messrs. Gaze's*, 134; *Messrs. Whitelegg's*, 134.
Omphalodes cappadocica, 254.
Orchis x maculata, 304; *latifolia*, 304.
Ornithogalum lacteum, 639.
Osmanthus Delavayi, 202, 235.
Oxalis adenophylla, 84; *emneaphylla*, 242.
Pachysandra procumbens, 189.
Paonia Montan, 244.
Papaver orientale *Lord Lam-bourne*, 259; *Princess-Eua*, 289.
Path, a half-wild, 605.
Paved garden, a, 567; a reader's, 569.
Pea, *Carters' Giant Potted Dwarf*, 58.
Peltandra virginica, 129.
Pentstemon confertus *ceruleo-purpureus*, 425; *Daydream*, 329; *humilis*, 425; *Menziesii*, 424; *Menziesii Scouleri*, 297.
Pergola, a simple; 592; at *Gravetye*, 494.
Philadelphus Coupe d'Argent, 116; *grandiflorus*, 154; *Lemoinei*, 456; *purpureo-maculatus*, 396; *Virginal*, 396; *Voie Lactée*, 396.
Phlox buxifolia, 86.
Phlox fruticosa, 428.
Phlox Douglasii, 477; *divaricata canadensis*, 477; *divaricata* *Laphamii*, 476; *subulata* *Illavina*, 242.
Phloxes, 40; border of, 111.
Phyteuma comosum, 85.
Pieris japonica, 606.
Plagiantbus Lyallii, 443.
Plum, the *Myrobalan*, 109.
Polyanthus at *Hillingbury*, 210; at *Spetchley Park*, 210; in woodland, 678; *Monstead*, 256.
Polygonum baldschanicum, 625; *compandulatum*, 603; *compactum*, 604; *equisetiforme*, 604; *polystachyum*, 604; *vacciniifolium*, 564.
Potato, *Ben Cruchen*, 528; *Great Scot*, 21; *King Edward*, 21; *Webb's* *King*, 58.
Primrose, the double *lilac*, 558.
Primula calceiphila, 97; *chionantha*, 57, 267; *chrysopea*, 295; *dariatica*, 185; *farinosa*, 185; *glaucescens*, 236; *Improved Giant White Star*, 81; *lithianensis*, 208; *Littoniana*, 307; *nutans*, 306; *obconica*, *Sutton's* *Salmon Queen*, 56; *pubescens alba*, 649; *pubescens* *Mrs. J. H. Wilson*, 215; *pulverulenta*, 644; *Purdonii*, 268; *rigida*, 295; *rupicola*, 293; *seemidiflora*, 268; *scholdii*, 208, 543; *Silver Star*, 175; *sino-listeri*, 421; *sino-purpurea*, 268; *sphaeroccephala*, 617; *spicata*, 306; *tibetica*, 104; *Unica*, 133; *Veitchii*, 209; *vincaeflora*, 538; *Wardii*, 104; *Winteri*, 99.
 Propagating pit, for trees and shrubs, 551.
Prunus Bileiana, 172; *Conradina*, 97; *Lanesiana* *Ukon*, 497; *pendula*, 219; *persica* var. *Clara Meyer*, 220; *serrulata* *Cherry's Weeping*, 220.
Pyraeanthus angustifolia, 110; *Gibbsii yunnanensis*, 52.
Pyrola uniflora, 5.
Pyrus Aria, 310; *Aucuparia munda* *subarachnoidea*, 556; *Vilmorini*, 576.
Ranuncula pyrenaica, 34, 414.
Rhodanthus maculatum alba, 67.
Rhododendron arboreum, hybrids of, 618; *ariculatum*, 559; *bulatum*, *Farrer's Variety*, 226; *calendulaceum*, 360; *calicelyx*, 120; *decorum* *Mrs. Messel*, 247; *emasculum*, 522; *Eximister*, 198; *Falconeri*, 199, 251; *intricatum*, 107, 512; *lutescens*, 207; *maximum*, 540; *monpinense*, 107, 522; *Ne Plus Ultra*, 96; *nudiflorum*, 553; *Nuttallii*, 232; *occidentale*, 361, 553; *Oleifolium*, 565; *Pink Pearl*, 408; *præcox*, 522; *prævernum*, 521; *racemosum*, 565; *sutchu-ense*, 159, 523; *viscosum*, 360.
Ribes sanguineum, 597.
Robinia hispida, 87.
Rockery, the water-side, at *Market Bosworth*, 535.
 Rock Garden, a newly built in water-worn limestone, 65; at *Hillingbury*, 561; construction, plans for, 94, 132, 158; the "Gazeway," 163.
Rose alba, 587; *Fargesii*, 590; *Hugonis*, 320, 589; *moschata*, 587; *moschata maculata*, 485; *rugosa*, 589; *Sweghizowii*, 588; *Willmottii*, 588.
Rose Albéric Barbier, 417, 463; *America*, 453; *Aurora*, 515; *Bessie Chaplin*, 369; *Betty Hulton*, 502; *Betty Uprichard*, 630; *Clara Curtis*, 635; *Coronation*, 593; *David Lloyd George*, 248; *Deception*, 223; *Fred J. Harrison*, 384; *General McArthur*, 586; *Golden Emblem*, 586, 666; *Hélène*, 533; *Innocence*, 636; *J. G. Glassford*, 673; *Joan Howarth*, 384; *Joanna Bridge*, 469; *Joan Waddilove*, 503; *Lady Inelquin*, 635; *Lady Roundway*, 344; *Little Joe*, 345; *Mable Morse*, 635; *Mme. Butterfly*, 224; *Margaret McGredy*, 514; *Mary Merryweather*, 533.

Rose Maud Cumling, 344; Mrs. Henry Bowles, 585; Mrs. Henry Morse, 586; Mrs. Tresham Gilbey, 223; Muriel Wilson, 635; Ophelia, 177; Phoebe, 635; Richard E. West, 514; Sanders' White, 593; Shot Silk, 502; The Garland, 532; Victor Waddilove, 515; Zépbirine Drouhin, 570.
Rose Garden, design for a pergola and garden house in the, 591; plan for a pergola in the, 590.
Roses, Mrs. Courtney Page's prize bowl of, 385; pruning, 146.
Rubus australis pauperatus, 410; biflorus quinquefolius, 645.
Salix Bockii, 609; Medemii, 131.
Saururus Loureiri, 233.
Savoy, fasciated leaf of a, 652.

Saxifraga bathoniensis, 30; Boydii, 147; Boydii alba, 147; cuspitosa, 31; Cotyledon catherhamensis, 318; Elizabetha, 95; Guildford Seedling, 30; Haagei, 183; oppositifolia, 182; Sartorii, 537; Tumbling Waters, 318.
Saxifragas, encrusted, 336.
Schizocodon soldanelloides ilicifolia, 422.
Scilla campanulata alba, 467.
Seakale, cultivation of, 653, 654.
Senecio Clivorum, 341.
Shortia uniflora, 182.
Silene acaulis, 641 (see note on page 670); acaulis pedunculata, 672; Armeria, 671; Hookeri, 538.
Skimmia japonica fragrans, 562.
Solanum crispum, 214.
Spiraea arborea grandis, 286;

Spiraea arguta, 286; Aruncus, 221; discolor, 286; Lindleyana, 285, 397; Thunbergii, 257.
Stock, East Lothian, 29.
Streamside garden, a, 145.
Syringa Wilsoni, 51.
Tolopea speciosissima, 19.
Terracing, plans for, 332.
Thomas, Owen, 299.
Thymus Serpyllum lanuginosus, 264.
Tiarella cordifolia, 388.
Trees, three in one, 417.
Tricholena rosea, 596.
Trillium grandiflorum, 659; rivale, 150.

SEWAGE DISPOSAL FOR COUNTRY HOUSES.—No emptying of cesspools; a perfect fertiliser; no solids; no open filters; perfectly automatic; everything underground. State particulars.—WILLIAM BEATTIE, 8, Lower Grosvenor Place, Westminster.

IRON and WIRE FENCING for Gardens, Tree Guards, Gates, Arches, Espallers, Rose Stakes and Ornamental Garden Iron and Wirework of every description. Send for Illustrated Catalogue. Also Kennel Railing and Poultry Fencing. Ask for separate lists.—BOULTON and PAUL, LIMITED Norwich.

ROCKERY PLANTS SPECIALITY.—List free. TERRY LEE, F.R.H.S., 16, Morden Rd., Stechford, Birmingham.

SUTTON'S VEGETABLE SEEDS.

By constant selection and re-selection, year by year, our choice strains are maintained at their highest standard of excellence.

Our Speciality for the Week: **SUTTON'S PIONEER PEA.** One of the finest first-early Dwarf Peas. Height about 2 ft. Per pint, 2/6; per quart, 4/6. **SUTTON & SONS, THE KING'S SEEDSMEN, READING.**

NOW IS THE TIME TO PLANT KELWAY'S LOVELY PÆONIES and the **KELWAY COLOUR BORDERS**, which include our world-famous Delphiniums, Pyrethrums, Lupines, Gaillardias, Phloxes, Pæonies, etc. Fine collection of Flowering Shrubs and Roses now ready. Write for descriptive Catalogues to **KELWAY AND SON, The Royal Horticulturists, Langport, Somerset.**

DOBBIE & CO., LTD., Royal Seedsmen, EDINBURGH, will send a copy of their 1923 Catalogue and Guide to Gardening, free, if this paper is mentioned.

BATH'S HOME GROWN BULBS.—New Illustrated Catalogue of the finest Narcissi, Hyacinths, Tulips, etc., as supplied to the Royal Parks and Gardens, with full cultural directions, is now ready, and will be sent post free on application.—(Dept. E), **R. H. BATH, LIMITED, The Floral Farms, Wisbech.**

BIRDS' BATHS, GARDEN VASES, SUN-DIALS, NESTING BOXES. Catalogue (No. 4) free.—**MOORTON, 65, Pearl Road, Walthamstow.**

PRIOR'S COLCHESTER ROSES, Fruit Trees, Shrubs, Gladioli, Dahlias, Alpines, Carnations, Herbaceous. Catalogue containing cheap collections free.—**D. PRIOR & SON, LTD., Colchester.**

CHOICE NEW CHRYSANTHEMUMS. Our New Catalogue of over 700 varieties, including 50 Novelties for 1923; also including finest Dahlias, Pelargoniums, etc., is now ready, post free on application.—**J. W. COLE & SON, Chrysanthemum Nurseries, Peterborough.**

DOWNER'S NEW RED LUPIN, 10/6 each. Apply for List.—**DOWNER (Dept. 2), Drayton Manor Nurseries, Chichester.**

WIRE BARGAIN! New Government Surplus! Ideal for training peas, beans, hops, tomatoes, small trees, wiring greenhouses, tying, fencing, etc. Waterproof, flexible, steel stranded and long lasting. Cash price, 19/6 per mile (full 1,760 yards). Send for trial lot or samples to-day.—**GREEN'S SURPLUS STORES, 205, Seymour Road, Lytham.**

PRIVET & THORN.—Also Rhododendrons, Heathers and Alpines. Send for List.—**HODSONS LIMITED, 58, Castlegate, Nottingham.**

THE DOG: MAN'S FIRMEST FRIEND.—How to choose and care for him, by A. CROXTON SMITH. A copy of this helpful booklet on the housing, breeding, feeding and care of dogs will be sent post free on receipt of 11d., addressed to The Manager, "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

THE GARDEN DOCTOR: Plants in Health and Disease, by F. J. CHITTENDEN, V.M.H., freely illustrated, 7/6 net, by post 8/-. A prospectus of this practical book will be sent by post on application to The Manager, "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

PLANT PESTS and PARASITES.—A useful booklet on garden troubles by HORACE J. WRIGHT is to be obtained from the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, W.C.2; 11d., post free.

TOMATO CULTIVATION: UNDER GLASS AND OUTDOORS. By R. GIFFARD WOOLLEY. A practical booklet by the Editor of THE GARDEN, 9d. net, by post 11d., Published at the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

GREENHOUSE PAINTING and GLAZING.—"Vitrolite," superior to White Lead Paint, 18/6 per gallon cans extra. "Plastine," the Imperishable Putty, 32/ per cwt. kegs extra; 7lb. tins, 4/3, post free; 14lb. tins, 5/6 each, carriage extra, tins free.—Full particulars from **W. CARSON AND SONS, Grove Works, Battersea.**

THE BORAGE ORDER

Its Place in the Garden Scheme.

THERE are individuals who will have nought to do with mass planting in any shape or form. There are others who do not believe that any plant can be effective unless displayed in large masses. The truth in this, as in many other instances lies somewhere between these two extremes. If we cast our minds back and revisualise some especially effective mass planting or wide natural grouping, we shall almost certainly find that the colouring of the group in question was on the "cool" side. Certain it is that if really "hot" colours—vivid salmons, dazzling oranges, vermilion tones or some of the brilliant rosy magentas are to be used in masses, the eye must be, as it were, led up to them by the use of gradually strengthening colour. It is, therefore, particularly difficult to use masses of strong colour in a small garden.

"What has this," it may be said, "to do with the Borage Order?" Simply this! That this order—the Boraginaceæ—contains many of the most effective blue-flowered plants for massing and blue is a colour none too plentiful in the garden, especially in the summer garden. There are also some plants, belonging mainly to the genera *Pulmonaria* and *Mertensia*, which are valuable for providing patches of rather quiet opalescent colour caused by the flowers opening rosy-pink and changing with age to blue. Yellow shades are found in the genus *Onosma*.

Undoubtedly the most popular genus in the Order is that of the Forget-me-not, *Myosotis*. It is to be found in practically every garden in the land. Some of the varieties of *Myosotis dissitiflora* are invaluable for spring bedding. The variety, *Roll of Honour*, illustrated on

page 2, received an award of merit in 1920. It is particularly fine, but after all, for bedding effect the cloudy mass of the easily grown Sutton's Royal Blue would be equally, if not more, effective. For producing charming masses of brilliant blue by the waterside, the Water Forget-me-not, *Myosotis palustris* is excellent. There is something very charming and unsophisticated about the bright blue, yellow-centred flowers in rather loose corymbs. This species will succeed well in semi-shade, quite away from water, if given well cultivated ground with a good proportion of humus. There are improved forms on offer. When purchasing seed of bedding varieties of Forget-me-not, the sort selected should largely depend upon the purpose in view. The "stricta" sorts—like miniature flowering Cypresses—are most effective where "dot plant" effects are wanted, but should not be used where broad or rather cloudy colouring is wanted.

There is a number of Forget-me-nots which are suitable for the rock garden, including *Myosotis alpestris*, which, in a damp, shady corner of the

rock garden, is very beautiful, but the form or hybrid called *Ruth Fischer* is even more beautiful. *M. Rehsteineri* is a neat species for wet land or moraine, very much like a miniature *M. palustris*. *M. Welwitschii* is an exceedingly easy and free-flowering species which readily naturalises itself. *M. albo-sericea* is a scarce and rather difficult kind, remarkable for its sulphur yellow flowers and silvery silky foliage. Very close to the true Forget-me-nots is the King of the Alps, *Ertrichium nanum*, so admirable in its native mountains, so difficult and unattractive in gardens.

If Forget-me-not is the best known genus of the Borage Order, the Alkanet (*Achusa*) must run it very close in point of popularity. Always a valuable blue flower, *Achusa italica* has been much improved during our generation. The two best known forms are probably also the most desirable. These are the rich gentian-blue Dropmore Variety and the azure Opal. A popular and desirable plant for massing towards the front of the border is *A. myosotidiflora*, with not specially handsome cordate foliage, but bearing

masses of small azure flowers over a long period. It will tolerate semi-shade, but succeeds in full sunlight. Very closely related to the *Achusas* is that glorious blue Hounds-tongue, *Cynoglossum amabile*, which, indeed, might almost be described as a finely coloured dwarf and compact edition of *Achusa italica*. *Myosotidium nobile* is the so-called Chatham Island Lily, which is hardy only in the south-west. Neither the robust leathery foliage nor the blue and white giant forget-me-not like flowers is very handsome. Were it not just on the border line of hardiness and rather difficult to establish besides, few would bother to grow it!

ACHUSA ITALICA DROPMORE VARIETY MASSED BY WATERSIDE.

BARBERRIES FOR FLOWER, FRUIT AND FOLIAGE

TO-DAY we have our rose garden, azalea garden, bamboo garden and rhododendron dell. Who among the host of readers of THE GARDEN will be bold enough to deny the possibilities and beauties of the barberry garden of the future. It will be a place of interest and attraction throughout the year! Not only are Barberries ornamental in foliage, flower and fruit, but many have gorgeous autumnal leaf-tints; while some are valuable evergreens. In others the leafless branches claim attention by reason of their colour and spines. Consider what we can do in the pleasure grounds and shrubbery borders with bushes of such varied foliage as *Berberis japonica*, with leaves up to 1½ ft. long, and *B. empetrifolia*, the narrow leaves of which are only ½ in. to 1 in. long. In habit of growth there is an equally wide variation from the diminutive *B. Thunbergii* minor and *B. buxifolia* nana, 1 ft. to 1½ ft. high, and the robust luxuriance of *B. aristata*, 10 ft. to 12 ft. in height and 18 ft. to 20 ft. in diameter.

The introduction of many new species from China during the last thirty years has more than trebled the value of the Barberries in the garden, their most important feature being the luxuriance and beauty of the fruits of a large number in autumn and early winter.

One may safely place the Barberries among the easiest of hardy shrubs to cultivate in the generality of soils. During the long spell of drought in 1921, nothing, with us, withstood the drought better than Barberries, although there were that season a goodly number of newly planted young bushes. The majority of deciduous species, having an abundance of fibrous roots, are fairly easy to transplant from October to March, when the weather is favourable and the ground in good condition for digging. The evergreen species are best planted in autumn or late spring. The only section calling for special comment is the pinnate-leaved *B. japonica* and closely allied species and varieties. Always try to have these placed in their permanent stations when young. If necessary to transplant fair-sized bushes, we find late April and May the best time. Moving with good balls of soil attached to the roots is, even then, necessary.

Barberries are by no means gross feeders; in fact it is surprising how well many of them thrive on gravelly slopes and steep banks, where it is not possible to do much soil preparation. In these cases a spring mulch of farmyard manure is worth considering. The least satisfactory soil to deal with is that which is heavy and ill-drained. A few cart-loads of gravel, broken bricks and mortar rubble freely worked in will do much to transform heavy ground into a *Berberis*-growing soil.

As a general rule it is a mistake to crowd Barberries when planting. So many of them have a distinctive habit of growth which gives them a beauty all their own, but which is easily destroyed or, at any rate, largely destroyed by close planting.

To bring out to the full the ornamental characters of the family, open and sunny positions must be the rule. There are exceptions, these being generally found among the evergreens. Few will deny pride of place to the Mahonia or Oregon Grape (*B. Aquifolium*), as the best evergreen shrub to clothe the ground beneath deciduous trees. Some shelter is necessary in many gardens when an endeavour is made to cultivate the Nepal Barberry (*B. nepalensis*) or Fortune's Barberry (*B. Fortunei*). Though hardier, the Japanese Mahonias (*B. japonica* and vars. *hyemalis* and *Bealei*), thrive best in sheltered, but not much shaded, positions.

The fact that it has been possible successfully to introduce and speedily to popularise the Chinese Barberries is abundant evidence of the ease with which they are raised from seeds. Were further corroboration required we have it in the wealth of hybrids raised through the chance cross-pollination of the best fruiting Chinese Barberries growing in close proximity at Wisley.

While the ease with which cross-pollination is effected may have its advantages, if we desire to perpetuate a particular species, unless the plant in question appears to be isolated, we must increase it by cuttings, layering or offsets (division), to be sure of true reproduction. In the same way the delightful Wisley hybrids must be propagated vegetatively for, being crosses, they will not reproduce true, though, of course, in raising

Darwin's Barberry scores in the richness of its golden blossoms. More upright in habit, also evergreen, it however does not quite equal *B. stenophylla* for a hedge, not being so readily pruned with the shears and more difficult to keep furnished near the ground.

B. Aquifolium.—Perhaps because it is planted largely under trees, the value of this Mahonia or Oregon Grape as a flowering shrub is not sufficiently well known. Under normal conditions it produces a wealth of yellow blossoms borne on erect racemes from March to May. These are followed in late summer and early autumn by an abundant crop of blue-black fruits, hence the name Oregon Grape.

B. japonica.—This is an imposing evergreen shrub of upright habit having, in early spring, erect

BARBERRIES UNDER FROST

seedlings from a hybrid there is always a chance of getting something better.

Taking a broad view of the Barberry family we find them possessing a distinct value for general planting in the pleasure grounds, shrubbery borders and the open woodland; a number give glorious masses in flower or fruit when planted in wide stretches; while others claim distinction as lawn specimens. Their value for a particular purpose and the best species and varieties can be best described by giving a short list under each heading, beginning with the—

BEST FLOWERING KINDS.

B. STENOPHYLLA has been aptly named the Queen of Barberries and is too well known to need a long description here. It occurred as a chance hybrid in the Handsworth Nursery, near Sheffield, about 1860, the reputed parents being *B. Darwinii* and *B. empetrifolia*. Wreathed in golden yellow flowers during April and May it is one of our best shrubs to plant in large masses. As an evergreen hedge shrub *B. stenophylla* responds very readily to the shears to keep it neat and shapely.

B. DARWINII.—This is the only rival to the last-named. It lacks the graceful arching habit, but

racemes of pale yellow blossoms with a delicious fragrance. *Bealei* is a hardier variety with larger leaves and *hyemalis* a winter-flowering form. All form attractive upright-growing bushes 6 ft. to 10 ft. or more in height.

B. POLYANTHA.—A deciduous Chinese Barberry, the true species is a wide spreading bush 6 ft. to 8 ft. or more in height. During June the arching branches are laden with drooping racemes of yellow blossoms. There are frequently fifty, sometimes over one hundred flowers in a raceme, and they are followed in autumn by quantities of salmon-red fruits.

B. VULGARIS.—The common Barberry of our hedgerows is getting rather overlooked in our desire to possess more of the exotic species. Some of the best forms, however, are unsurpassed by any of the deciduous species when full of yellow blossoms during May and again with rich red fruits in autumn.

B. AGGREGATA and the closely allied *B. Pratteni* are distinct in having erect inflorescences freely borne at the ends of the shoots, thus showing to the best advantage both the yellow flowers and fruits. *B. yunnanensis* has a rather larger flower than most of the deciduous Barberries, growing up to 5 ft. or 6 ft. in height. The clusters of yellow

flowers are attractive in early summer and are followed by salmon-red fruits in autumn.

FRUITING BARBERIES.

Among these the Wisley hybrids, Autumn Cheer, Fireflame, Sparkler, rubrostilla and Sibbertoft Coral, lead the way, giving us a wealth of colour and interest in the garden during autumn and early winter. These are apparently the result of chance cross-pollination between the best of the newer Chinese fruiting species, which include *B. polyantha*, *B. subcaulata*, *B. Staphana*, *B. Wilsonæ*, *B. yunnanensis*, *B. aggregata* and the variety Prattii.

Selected forms of our common Barberry (*B. vulgaris*) deserve much more attention from planters. The fact that they grow so freely in the hedgerows is abundant evidence of their hardy and accommodating nature. For sloping banks, the lake-side and on the edge of the woodland, picture the effect of bushes laden with rich red fruits in autumn and early winter!

Unlike most berries or fruits, those of the Barberries (not the Mahonias) have an acid taste which the birds do not care for. Consequently we are able much longer to enjoy their beauty.

EVERGREEN KINDS.

Many of these are beautiful and interesting shrubs at all seasons, though particularly valuable and ornamental in winter. Three of the best, *B. stenophylla*, *B. japonica* and *B. Aquifolium*, have already been noted as valuable flowering shrubs. In addition to the value of the last named in the garden, its use for cutting is seen on every hand in the streets of London and the suburbs. The quantity sold in Covent Garden must amount to tons every week in winter. The foliage turns naturally to a bronzy-red hue in winter but, by placing the stalks in cold amine dye, the colour changes to dark red. In the home it is most valuable for vase decoration associated, among other things, with *Jasminum nudiflorum*, *Hamelis mollis* or *Forsythia spectabilis*.

B. SARGENTIANA is a particularly tree-growing and hardy evergreen, introduced from W. Hupch by Mr. E. H. Wilson in 1907. When home recently, Mr. Wilson said it was the only one among the evergreen Chinese species which had proved hardy in the Arnold Arboretum. The oval leaves vary from 2ins. to 5ins. long and 1in. to 1½ins. wide.

B. CANDIDULA forms a dwarf, close-growing bush, usually under 2ft. in height, the leaves shiny, dark green above and distinct blue-white beneath. For the front of the border or the rock garden it is a valuable and distinct addition.

B. GAGNEPAINI is a graceful and interesting shrub with distinct linear-lanceolate leaves, having undulating spiny margins, yellow flowers and blue-black fruits. In a wild state Mr. Wilson found it growing in Western Szechuan 100 to 200 ft. in height.

B. VIRENDOLENSIS is also from Western Szechuan, growing to 100 ft. in height, the leaves dark green above and blue-white beneath. The twigs are covered with a dense covering of small, round, orange-brown, scaly scales.

Autumn colouring is very good with Barberries. Each shrub has its own special preference. *B. yunnanensis* and *B. subcaulata* are excellent for colouring. *B. polyantha* is tall. Sprays cut for decoration of the house are especially so, and colouring best in appearance. *B. candidula* and *B. Thunbergii* are the best for colouring. *B. polyantha* has a month of its brilliant yellow, red, scarlet and crimson foliage in autumn. *B. polyantha* is another Chinese Barberry with golden red and yellow foliage, while very similar in colouring also is *B. dictyophylla*.

A selection for the rock garden should include *B. Wilsonæ*, *B. Thunbergii minor*, *B. empetrifolia*, *B. Darwinii nana*, *B. candidula*, *B. buxifolia nana*, *B. verruculosa* and last, but perhaps the most important of all, *B. concinna*. This has the largest and most fleshy fruit of any Barberry, approaching an inch long and correspondingly thick. It was first introduced by Sir Joseph Hooker from the Sikkim Himalayas about 1850. Low-growing and spreading in habit, it has rich green leaves which are white beneath and when raised on the boulders of the rock garden, it is very distinct and interesting.

In addition to the spiny character of the deciduous stems in winter, two species appear very prominent, the red twigs of *B. virescens*, and the grey-white stems of *B. dictyophylla albicaulis*.

These notes would not be complete without reference to one of the most robust of all Barberries, *B. aristata* of the Himalayas. It is a tall and wide-spreading shrub for the pleasure grounds, attractive in flower and fruit. The variety *Chitria* has the flowers in panicles (not racemes) and is an equally robust growing shrub.

The Kew collection of *Berberis* numbers about one hundred and thirty species and varieties. A. O.

GARDEN HEDGES

Planting and Early Treatment.

A WELL cared for hedge of any kind of suitable plant adds considerably to the general appearance of the garden. During the past twenty-five years I have visited hundreds of gardens, with the main object of assisting to award prizes in competitions. Even on private visits to gardens of larger extent I have observed good and bad hedges. In the case of those entered for competition the condition of hedges and paths were duly considered and, in many instances, made all the difference between success and failure for the main prizes. From my youth I have made almost a hobby of planting and training hedges in field and garden.

The present is a suitable time to plant new hedges or to renovate old ones, but only in special cases would I undertake the work of renovation, for patched hedges are seldom satisfactory; it is much the better plan to plant entirely new ones. Unless the position warrants it, the building up of a bank, on which to plant the hedge, is a mistake. Where ground is swampy or naturally very sour, a bank is advisable; also, where the hedge is required to be of a certain height and level, across deep hollows. In naturally dry places the planting of a hedge on a bank handicaps the plants

considerably in dry seasons and, always, the banks form suitable ground for coarse grasses and many kinds of weeds, besides entailing as much labour to keep tidy as the hedge itself.

A hedge with even, neatly trimmed sides right down to the level of the lawn, field or wood, always presents a pleasing appearance and, furthermore, is an effective guard to the ground enclosed.

THE BEST KINDS OF PLANTS TO FORM A HEDGE, WITH THE DISTANCES APART TO PLANT,

Beech	1ft. apart.
Berberis Darwinii	18ins. ..
„ stenophylla	18ins. ..
Cupressus Lawsoniana	1ft. ..
Holly	1ft. ..
Common Laurel	18ins. ..
Portugal Laurel	18ins. ..
Myrobalan Plum	1ft. ..
Thorn	6ins. ..
Evergreen Privet	6ins. ..
Thuja Lobbi	18ins. ..
English Yew	18ins. ..

PLANTING.

Usually one finds the natural soil rich enough, but, where it is decidedly poor, the greatest economy

A HEDGE OF BERBERIS STENOPHYLLA.

is assured by adding really rich soil and also some well rotted manure. I like to put in a reasonable quantity of the latter where the soil is good, as thereby one secures a hedge full of strong shoots near the base and, afterwards, it is a very easy matter to build up a handsome hedge by timely and judicious training and cutting. The height at planting should be about 18 ins., as small specimens possessing plenty of fibrous roots, grow more quickly and, as a rule, become established sooner, than those twice that size. Privet and Thorn especially should be cut fairly hard back at the time of planting or before new shoots grow. Near grass Privet may be used, but it is undesirable where crops are to be grown quite close up to the

hedge as it impoverishes the soil considerably and unduly robs the border crops.

During the first year after planting the chief pains should be to keep the young plants as clean as a row of Carrots in the vegetable quarters; to attend to watering if a spell of dry weather comes, and to firm the soil around the plants by treading directly frost has thawed and while the ground is dry. Twice, during the late spring and again in September, some cutting of the young shoots will be advisable. The hedge must be built up so that the lower branches will touch or almost touch, the ground and the hedge at the base, when fully grown, will be a few inches wider than across the top.

GEO. GARNER.

THE WINTERGREENS

THE Wintergreens (*Pyrola*) are one of the finest but, also, most difficult genera to grow in a garden. Few are those who can shew good patches of them in their collections and fewer still those who can grow them in the rock garden. They are as capricious as any high alpine, and seem to resist the gardener's tending. Of course the luxuriant *Pyrola rotundifolia*, the best of our European species, is relatively easy to introduce to the garden, and this especially in England, where I have seen large carpets of it. The plant is vigorous, makes in nature immense patches and bears splendid evergreen, leathery foliage, shining bright green above, reddish beneath, and this is in itself extremely decorative. The flower scapes are from 6 ins. to 10 ins. long and bear eight to thirty flowers in a terminal raceme, forming a spike similar to that of the Lily of the Valley. Hence its French name "Faux-Muguet." These flowers consist of creamy white waxen cups with orange scarlet style and anthers. They have a very agreeable scent. *P. rotundifolia* grows in shady woods under deciduous trees in ground rich in humus. Sometimes it is found on steep banks with a north aspect in heavy and damp soil (for instance, along the road leading to the Marchairuz path in the Jura). It is found throughout Europe, in Northern Asia and North America.

High up in the Alps the Wintergreen is *Pyrola chlorantha* (Sweet), which has greenish flowers, sparsely distributed along the stem, and smaller leaves. *P. arenaria* (Scheele) is a minute form of the type growing in the Val de Bagnes (Valais). *P. minor* (L.) is a rather small kind, with round leaves, shortly stalked. Its pink flowers (ten to fifteen of them) are disposed in a short spike. In this species the style does not project beyond the corolla. It grows in the woods of the mountain region. *P. media* (Sweet) is a very rare intermediate form between the last and *rotundifolia*.

In North America many nearly allied forms grow. *P. americana* (Sweet) seems to me to be only an American form of our *rotundifolia* (see the figure of it published in "Wildflowers of New York," Vol. I, page 190). *P. asarifolia* (Michx.) has reniform leaf blades, usually wider than long, and a raceme of nodding, purple or rose-coloured flowers one-half to two-thirds of an inch broad. It is a sub-Arctic species from the cold, moist woods and swamps of the north. *P. elliptica* (Michx.) has its leaves longer than broad, elliptical in shape and thin, with ten to twelve wax-white flowers, smaller than those of *rotundifolia* but borne on a long, erect stalk. *P. uliginosa* (Torr and Gray) has small foliage and small pink flowers, furnished with long, slender styles; these flowers are sparingly disposed (ten to twelve of them) along a feeble stalk. The plant is found in the bogs and marshes of North America,

Pyrola secunda (L.) is the commonest of all, and grows as a weed in the mountain, or even in lowland, forests. Its handsome, narrow foliage,

CHOICEST OF WINTERGREENS, PYROLA UNIFLORA.

shining light green in colour, adorns otherwise barren places of the great woods where it always grows in dry, shady corners. Its flowers are greenish, small, disposed in one-sided (unilateral) racemes and are, of course, of little decorative value for the garden. It is, however, the most difficult of all to acclimatise, and I must confess that I never could succeed with it.

Most precious of all, however, is *Pyrola*, or rather *Moneses* if we follow Asa Gray's nomenclature, *uniflora* (L.). It is a dear little thing, slender and delicate, which grows here and there in woodland, in damp, sandy places, never abundantly. The leaves are orbicular, strongly nerved, yellowish green and very thin; the flowers are relatively large, looking as if made of creamy white wax and are solitary on little stalks. Its fragrance is among the most exquisite of all the plant perfumes. It resembles somewhat a whiff of orange blossom or the scent of the Gardenia or Tuberose. To have some of these on one's table is to provide a fragrance which it is hardly possible to better. In cultivation, however, the plant is one of the most difficult of all. Here in our dry atmosphere we never could acclimatise it well

but at Scampston Hall, where Mr. St. Quintin grows lots of rarities, about which I hope some day to write, it seems to me remarkably well established. He grows it in pots. The picture below is from a photograph of one of them. This curious plant grows naturally in mossy, rather light and sandy ground between roots and among old wood. Sometimes the site is very dry, or seems to be; in other cases it is wet. One cannot give the exact conditions of its growth, as it has so many seemingly contradictory habitats. It belongs to the flora of the northern hemisphere, is a rather sub-Arctic and Arctic plant and grows abundantly on the banks of the Baltic Sea wherever there is woodland. In North America it goes far into the Arctic regions.

There is another section of *Pyrolas* bearing their flowers in heads instead of spikes or in umbels which has been called *Chimaphila* by the American botanist Pursh. They all but one belong to North America. *P. umbellata* (L.) grows here and there in the woods of certain parts of the North of Europe. It is to be found near Zurich in

Switzerland in one little corner where it is protected by law. I found it abundantly in the Darmstadt forest in Central Germany and in some nutrequented places in the Forests de Fontainebleau and Rambouillet, near Paris. It is a dwarf shrub, trailing upon the soil and running as does *P. secunda* with long underground stolons, and it makes in one or two spots very nice colonies of dark green foliage. The leaves are serrate, oblong and shining, and something like those of the Box, but disposed at the top of the stalks as are those of *Polygala Chamæbuxus*. The flowers, which are produced in May and June, are deep pink in colour and rather small, but grouped in little heads. It is of easy cultivation here, and wants only a moist and half-shady place in light and porous soil. *P. (Chimaphila) maculata* (L.) is American too, but it has been found, curiously enough, in the woods of Fontainebleau and Rambouillet as well as the species last mentioned, but in very rare instances. Its foliage is the one thing showy about it. The leaves are beautifully marbled with grey, pink and green, and are serrate. The serrations are fewer than in *P. umbellata*.

Flora, genera.

H. CORREYON.

ANTIRRHINUMS

January Sowing for June Flowering.

THERE is no longer need to commence an article on Antirrhinums with an elaboration of their claims to popularity, for the propaganda of several years past has accomplished its purpose and the charms and sterling merits of the modern race of Antirrhinum have carried it to the vanguard of popular flowers. The task of the tutor is now to impart details of cultural methods or systems that will help the amateur to attain the greatest possible measure of success, so that the vogue of the Antirrhinum may run no risk of shipwreck through misguided zeal or the errors of inexperience. Thus far the Antirrhinum is a plant of rude health and vigorous constitution, singularly free from virulent diseases and irritating weaknesses, and it is of the utmost importance that it should be kept so.

It is far from my desire to indulge in scaremongering, for no useful purpose could thus be served, but a timely word of gentle warning may be productive of beneficial results, while delay in uttering the word until the day of trouble arrives would be tragic.

One of the penalties of exceptional popularity in any plant is that rapid, and more or less unnatural, methods of propagation are bound to be practised, endeavours will be made to prolong the season of flowering by various methods of treatment, and these things, coupled with excessive feeding, are calculated to weaken and undermine the plant's vigorous constitution and render it susceptible to disease.

My plea is that whoever may handle Antirrhinums, either for purposes of trade or for production of exhibition flowers, will be content to treat their stocks rationally, reasonably and as nearly as possible on natural lines.

One essential is that propagation should be mainly from seed and not cuttings, seed being a more natural method of increase and consequently calculated to maintain a stock with vigorous constitution.

Furthermore, anything in the nature of forcing will weaken stock, and it is extremely unwise to hasten the growth of young plants by growing them in an artificially produced high temperature. In the first few weeks of the year, when glasshouse work comes on with a rush, and the temptation is to delay seed sowing until a while, and then to rush seedlings along as rapidly as possible under fire-heat in order to make up for lost time. Such tactics are very prejudicial to the health of the young plants and, moreover, a soft, unduly

hastened growth is not capable of carrying good flower-spikes.

Some few attempts have already been made to get Antirrhinums to flower in winter. Such efforts are only deserving of censure and condemnation. Much as we may delight to see Antirrhinums, we should prefer to do without them in the winter

the summer and autumn. The soil for the seed sowing should be gritty, with some admixture of lime. The seed should be sown very thinly, and the young seedlings should be pricked off before they become at all crowded.

On all possible occasions ventilators should be opened, and when the worst of the winter is over the plants may be transferred to a cold frame. Here advantage may be taken of fine mild days to remove the light from the frame, covering at night, but even then leaving a little ventilation on.

We are already getting a multitude of named varieties of Antirrhinums, and the time approaches when we shall require a Synonyms Committee or some scheme to pick out the best of each colour and to discard some of the superfluous names.

As a selection of distinct and excellent varieties any of the following may be grown with confidence.

ADMIRATION.—A very showy variety with a white tube, bright coral red standard, lip and frill, with a clear yellow blotch on the nose.

CARMINE KING.—A brilliant carmine self of fine habit and very free flowering.

EMPRESS.—This is a very fine flower of glowing velvety crimson. The pipes are of good size, and the plant is of rather dwarf, compact growth.

HARMONY is of tall, upright growth, producing long, upstanding spikes of bloom. The colour is a combination of rosy pink and terra-cotta with an overlay of pale yellow.

MONARCH.—I consider this by far the best crimson up to date. It is an exceptionally tall grower, the stout, erect stems frequently exceeding 4ft. in height. The individual blossoms are large and of a very rich velvety crimson with dark coppery foliage.

PRIMA DONNA.—A great favourite that appeals to most people, both on account of the size and beauty of its form and the fascinating beauty of its colouring, which may be described as apricot taw with a blush of peach pink.

Of the flame or orange scarlet shades either Bonfire, Torchlight or The King are excellent, while in whites The Bride for a dwarf bedder and Queen Victoria for a tall, long-spiked variety are very satisfactory. Yellow King is the richest yellow, but equally pleasing is Yellow Queen in a lighter lemon yellow shade. A. J. MACSELF.

A BORDER OF ANTIRRHINUMS.

THE WINTER SWEET

THERE is always a delightful element of uncertainty about the date of flowering of that beautiful shrub, the Winter Sweet, *Chimonanthus fragrans*. Dependent upon the weather, the deliciously fragrant blossoms may gladden the short November days or tarry until the brighter days of March; all that we can be quite sure of is that the flowers will come, there is no doubt about that, for it is extremely hardy. The habit is deciduous and the plant attains a height of about 8ft., being excellent for clothing walls, as this position ensures just enough protection to enable the flowers to open early and well. The leaves are deep green, rough to the touch and slightly downy when young. The flowers are solitary and borne on very short stalks from the joints of the shoots made during the previous summer; the sepals and outer petals a curiously transparent yellow green, followed by a gourd-like seed that remains attached to the plant for a considerable time. Cut a few sprays from the plant when the flowers begin to expand, place them in a vase of water in a warm room and one can have no doubt as to why the plant obtained the name of Winter Sweet; its fragrance is delicious and amply repays the ground occupied, more especially when one remembers the season at which the flowers are available.

rather than ruin them with hothouse treatment. The Antirrhinum is a hardy plant. Let us be content to keep it so and treat it as such. I saw last year a big batch of a special variety grown for seed under glass. The plants were badly attacked by a fungus, which examination showed to be of *Cladosporium* character. The disease, in my opinion, gained a footing simply because the plants were weakened by glass-house culture, but the seed from those diseased plants may very probably carry the spores of the fungus and produce young stock that is doomed to early attack of disease and utter collapse. It is so unnecessary to resort to these unsatisfactory tactics. All that is required to ensure a fine display of bloom onward is to sow the seed early and let the seedlings grow along as steadily as possible in a house only sufficiently warmed to keep out frost and maintain a fairly dry atmosphere. Seed sown in January and grown cool will produce excellent plants for putting out, weather permitting, in April, and these will begin to bloom in June, carrying a full crop of flowers right through

THE NEWER VIOLAS

DURING the past few seasons the Viola has been much improved, perhaps the most important advance being the production of a type that combines the tufted habit of the bedding strain with its free-flowering character and is capable of giving blooms large enough for exhibition purposes. In the following list are included the "cream" of the recent introductions.

Andrew Gibb (Milligan, 1923).—A medium tufted habit. Free flowering. Will make a good bedder. Very large bloom. Rich cream self. Rayless.

Annie Jobson (Harrison, 1923).—Purely a bedding variety. Very dwarf and compact habit. Very free flowering. An attractive colour, rich dark crimson striped and splashed with light rose.

Donald Ferguson (McAlpine, 1922).—One of the largest Violas in cultivation. Perfect form and splendid under petal. Texture smooth and glossy. Deep violet blue shading to crimson purple, and distinct yellow eye.

Ella L. Blair (MacColl, 1923).—A pretty blend of mauve, lavender and cream, the colours being artistically intermingled around a creamy white centre. Very good form and texture.

Elma Millar (Stevenson, 1922).—A huge petunia purple, virtually an improved Milton Junbo. It is a very fine grower and the blooms are of fine finish. Perhaps the best and largest of the dark Violas.

Eddie Cook (Milligan, 1921).—Although this Viola is of rather straggling habit, it is free flowering. It is the best of its colour, glossy purple with upper petals shading out to pale heliotrope.

Isobel McGregor (Milligan, 1923).—Very tufted habit and free flowering. Good both for bedding and exhibition. A new colour, creamy white ground marbled with pale heliotrope with a deeper edging.

Jean Gibb (Milligan, 1922).—Very tufted habit. A fine bedding variety as well as useful for

exhibition. It is a model flower, always of smooth texture and the purest white.

Jean Marr (Stevenson, 1922).—A variety with a nice habit, giving upright blooms on long stems. Good shape and texture. French white, lightly shaded blue.

Jeannie Jamieson (Stevenson, 1922).—Good habit. A very daintily coloured flower after the colour of the popular variety Mrs. J. Smith. It is a lovely shade of light heliotrope lightly suffused over a white ground.

Lizzie Watson (Stevenson, 1921).—Of first-class habit and very free flowering. Recommended more for bedding than exhibition. Colour pure rayless ivory white, after the style of Mrs. C. Milligan.

Malcolm Milner (Milner, 1922).—It is of rather straggly growth but very free flowering. When at its best it is very beautiful, but it sometimes fails in the lower petal. Deep primrose with bright sky blue edge and clear yellow eye. Petals of fine texture.

Mollie Gibb (Milligan, 1922).—Medium tufted habit and very free flowering. It produces immense flowers of a lovely shade of pale primrose edged with heliotrope. One of the best of Mrs. W. R. Milligan type.

Mrs. Jas. Ritchie (McAlpine, 1922).—One of the finest of recent introductions. It is identical in colour with Mrs. W. R. Milligan, pure rayless white with a dainty edging of sky blue, but it is half as big again as this variety and easier to show. It has a very good habit.

Mrs. Hugh MacColl (MacColl, 1923).—A large glossy cream self of fine texture and good build that seems very promising.

Mrs. Andrew Kerr (MacColl, 1923).—Another good new variety from the same raiser. Of fine build, form and texture. Colour creamy white with a narrow edge of blue.

Mrs. Andrew Stevenson (Stevenson, 1921).—The most sensational Viola of recent years. It has an excellent habit, perfect build and in every

way it is a flower of fine quality. The flower is rayless, a deep yellow with a heavy edging of deep heliotrope on the lower petals and the top petals are suffused with the same rich colour.

Mrs. D. Stevenson (Stevenson, 1921).—A daintily coloured Viola, pure white with a clean edge of pale blue. It has a fine habit and is possibly the best flower of this class, being less inclined to sport than its rivals Mrs. J. Terris and Bessie Ferguson. Winter the cuttings in light leafy soil.

Miss Annie Morton (Macfadyen, 1922).—Dwarf habit and short jointed. Dark glossy crimson marbled with purple and rose.

Mrs. Jas. McKillop (McKillop, 1922).—Good habit. Suitable for bedding and exhibition. Large bloom of a rich shade of rose and particularly fresh looking.

Mrs. W. Penman (Penman, 1922).—A promising variety. Good habit. Very large thick-petalled flower. Rosy purple self.

Margaret S. Penman (Penman, 1922).—Medium habit. A very fine variety, possibly the best of the pale yellows. It is very large, of splendid shape and has extra long stems. An ideal flower for exhibition.

Maggie Rutherford (Macfadyen, 1921).—A strong grower but of rather straggly habit, still up to the present the best of its colour—rose with a soft lavender sheen.

Mabel Spencer (Ollar, 1922).—A lovely colour, quite remarkable, rayless white centre with broad margins of sky blue and distinct yellow eye. It is a large flower of fine texture and the habit is quite good.

Mary Cochrane (Cochrane, 1923).—A very large flower of pretty colouring, deep cream edged with heliotrope and the top petals mottled with the same colour. It is of good form and texture.

Nancy Harrison (Harrison, 1921).—A very strong grower of rather straggling habit, but bearing blooms of enormous size and fine substance. Rose ground striped with crimson purple. One of the best of the striped Violas.

Nurse Stevenson (Stevenson, 1921).—Although the habit of this variety is not always of the best, it is a lovely flower of exquisite colouring, clear rayless yellow with a perfect edge of sky blue.

Orange Perfection (Davidson, 1923).—A deep orange self, the deepest of its colour yet raised. It is rayless and has a fine under petal. The long, strong stems make it invaluable for vases.

Peggy Barr (Milligan, 1921).—Of medium tufted habit and free flowering. Possibly the largest Viola in cultivation. Dark purple with a narrow edge of lighter purple.

Peggy Ramsey (Cochrane, 1923).—A lovely flower of fine form and texture. The colour is cream shaded with heliotrope with a rich edging of mauve all round.

Pride of Darras (Harrison, 1923).—A very striking new bedding variety with a splendid habit. The flowers stand up well above the dark foliage. They are of a lovely rich shade of deep purple, the colour gradually softening in shade towards the centre till it gradually disappears into a white central zone. This will prove one of the best bedding varieties in commerce.

Rev. Donald Grigor (Macfadyen, 1922).—A well formed flower of good texture. It is a buff yellow self, rayless, with a clean eye.

Rita Stevenson (Stevenson, 1921).—The best habit of any of the exhibition Violas. One of the prettiest varieties ever raised. It is unique in colour, pure white edged with bright carmine. Not quite the size, texture or build of Mrs. A. Stevenson, but very telling when well grown.

Ronald Mason (Mason). A variety of good habit and quite a classical flower in every respect. It has a cream ground with a broad band of light

NEW VIOLA PRIDE OF DARRAS.

lavender. This *Viola* deserves to be more widely grown.

Sarah Botham (Milligan, 1922).—Very tufted and free flowering. Fine both for exhibition and bedding. Creamy white with a lavender edge. It inherits all the good points of Mrs. W. R. Milligan, from which it is a seedling.

Sergt. Turnbull, V.C. (Milligan, 1923).—Tufted habit. Free flowering and an ideal bedder, also good for exhibition. Creamy white with a narrow edge of blue all round. Another beautiful seedling from Mrs. W. R. Milligan.

Tangerine Harrison (Harrison, 1923).—Another fine new bedding *Viola*, which is aptly described in the name. It is a very striking tangerine self and rayless. Compact habit and free flowering.

Thomas Russell (McAlpine, 1923).—A strong-growing striped variety which is a seedling from Sir E. Grev. It has long stems and a neat eye. It gives a large round flower with rosy purple markings on a rosy pink ground.

William Gibb (Milligan, 1923).—Mr. Milligan tells me that he considers this variety the best of its colour, a glossy primrose self, perfectly rayless. It is very tufted and yet produces blooms of the largest size.

William Wallace (Milligan, 1922).—Straggly habit till it becomes established. The best blooms are obtained from the side growths. It is creamy white with a band of blue all round the under petal and the top petals are splashed with the same colour.

The following would make a strong all-round dozen from the above: Andrew Gibb, Jean Gibb, Mollie Gibb, Mrs. Jas. Ritchie, Mrs. A. Stevenson, Margaret S. Pennan, Mrs. D. Stevenson, Peggy Barr, Nancy Harrison, Rita Stevenson, Ronald Mason and William Gibb, with *Pride of Darra* added for bedding purposes. NORMAN LAMBERT.

THE OLD DOUBLE WALLFLOWERS

It does not always follow that a plant is worth growing because it is ranked among the old-fashioned flowers which used to delight past generations. Many of these have really been superseded by choicer plants, yet there are goodly numbers which possess an intrinsic value apart from the old-world atmosphere which their traditions convey to us. Such are, I think, the old double varieties of *Cheiranthus* *Cheiri*, the Wallflower. They have not, it is true, the grandeur of some of the modern double Wallflowers, but, on the other hand, they are more perennial, and they have a delicious fragrance which is not surpassed by that of any of the single varieties. Some of them must have been in gardens for many, many years, but they are now comparatively rare. This is probably due to the fact that they require to be propagated from cuttings, as they do not bear seeds; and, although "perennial" and "lasting usually" for some years, they have in common with most of the *Cheiranthuses*, a comparatively short tenure of life; though their demise may be delayed by cutting them fairly well back annually after flowering. The cuttings strike easily in pots of sandy soil under glass.

How many of these old double Wallflowers have been in cultivation I cannot say, and it is none to the point to name those which are still in commerce. Of these one of the sweetest and best is called *Harpur Crewe*, which, although of earlier date than the departed flower-lover whose name it bears, was brought into renewed prominence by him. It has small quite double bright yellow flowers in moderate-sized spikes, and is

of a most delicate perfume. A fitting companion to this is the one known as the old Double Black. It is not really black, but is of a deep blood red and has all the fragrance of the finest of our blood red single Wallflowers. It is quite scarce in gardens, and is far from plentiful even in nurseries nowadays. Still another variety exists, and

this has golden yellow flowers larger than those of *Harpur Crewe*. It has all its good qualities, however, and those who wish to have these double Wallflowers should endeavour to procure all three. It remains to add that these plants stand longer if planted in poor, dry, but firm soil and in a sunny situation. S. ARNOTT.

NOTES OF THE WEEK

IN wishing all readers of *THE GARDEN* a very happy and prosperous New Year, the Editor begs to call attention to the Contents Table on page iii, at the beginning of the paper. This feature will be included in future issues and should facilitate subsequent reference to articles of which no note was made at the time of reading. It will not, of course, supersede the Index, which is given with the last issue of each volume.

The Hardy Plant Society. Many readers will, we are sure, rejoice to hear of the renewed activity of the National Hardy Plant Society. Formed in 1910, it was just fully embarked on a programme of useful work when war cut short its activities. Nursery stocks of herbaceous and alpine plants which are the "lives" in which, at present, the Society specialises, are back at normal and there is no reason whatever why it should not do great things. It is felt that either the Chairman or Secretary of the Society should reside in or near London and an effort is to be made to carry this feeling into effect. A special committee has been appointed and will report to the annual general meeting of the Society on the 30th inst., suggesting various alterations to the "objects, rules and bye-laws" of the Society, to bring them into touch with present day feeling. It will also lay before the meeting a programme of work for the coming season, which will include the issue of a journal at intervals. All lovers of hardy plants who reside within reach of London should make a point of attending the meeting, which will be held at the Royal Horticultural Society's Hall, Vincent Square. Membership of the Society can be obtained for an annual subscription of

7s. 6d., and everyone interested in hardy plants—not only those who are interested in them for exhibition—should make a point of joining at once. The Hardy Plant Society is affiliated to the Royal Horticultural Society and is in no way intended to be a competitor to that august body or indeed to any other established horticultural society. Your 7s. 6d. *note*, so that the Society, which has at present 440 or so in hand, can map out its programme for 1923, will be worth 15s. subscribed *after* the meeting. The Secretary's address is Dactylis, Clifton Park Road, Caversham, Reading.

The Seed Order.—Many enthusiastic amateur gardeners spent odd hours of the Christmas holiday digesting (and enjoying) the handsome new editions of the big seedsmen's catalogues. Not all flower lovers are *quite* so enthusiastic as that, but it behoves every keen gardener now to look into the matter of this year's seeds. It is advantageous both to buyer and seller that orders should be placed early. The benefit to the seed-man is obvious. The buyer gets the advantage of securing just what he wants, not what the seller has left—and prompt delivery.

The Picture.—Of all winter-blooming flowers, none is more beautiful than *Cyclamen hyemale*, which is often sold as *C. Coum*, but is readily differentiated by the white marbling on the foliage. The true *Cyclamen Coum* is a less common species with foliage of a uniform black-green, but the mottling of the species illustrated is at once effective and cheerful. Hardy *Cyclamens* are quite easy to raise from seed. The treatment is similar to that usually afforded to the Persian (greenhouse) *Cyclamen*.

A FINE CLUMP OF CYCLAMEN HYEMALE.

CORRESPONDENCE

LIFTING MICHAELMAS DAISIES.

IN his most interesting article on Michaelmas Daisies the Rev. Joseph Jacob (December 2, 1922) asks if they can be flowered in pots. They can be most successfully grown that way. For several years I used to grow them here for the autumn decoration of a long glass corridor. My method was, about February, to put an old plant of each variety wanted in a cool house, just covering the plants with any light soil. As soon as the young shoots had grown sufficiently they were taken off and put singly in 3in. pots, stood in a propagating frame until rooted, after which they were placed in a cold frame until weather conditions allowed their being planted out. An open spot in the kitchen garden was given them for the summer months. Care was taken to keep them to single stems, and also securely tied. It is not done and they are allowed to fall over and the stems to stiffen, it is almost impossible to get them up again into nice-shaped plants. Towards autumn, just as buds began to shew, they were carefully lifted and potted into 8in. or 10in. pots, according to size. They were then stood behind a north wall and frequently damped over with the syringe until the roots had taken hold of the soil, when they were given a more open position until the flowers began to shew colour. They were then placed in the corridor, where for three weeks or a month they bloomed profusely. I noticed the colours were not quite so bright under glass as outside. On the other hand, the outside plants often had a most sorry, bedraggled appearance owing to wind and rain. It was a pleasure then to see the bright, clean look of the inside ones.—H. REYNOLDS, *Gt. Yarmouth*.

AN UNUSUAL TORCH LILY.

AS one strolls around other gardens it sometimes happens that one comes across a plant which fascinates by its own peculiar qualities. One feels that one simply must possess it and—in this connexion—I have fallen a victim to *Kniphofia comosa*, one of the most unusual and distinct of all the Red Hot Pokers. The plant is of good habit with rather narrow, pale green foliage and tall, thin flower-stems, most of which push out a small subsidiary spike from the side so that, when the main inflorescence is past, a further period of usefulness is still contributed by the main stem. The flowers are in the form of a short bottlebrush-like head of a brilliant carmine orange colour that glows with a wonderful firelight sheen which, in spite of their small size, stands out well right across the garden. The manner in which the buds open reverses the usual procedure of these plants, for they begin to open from the top of the spike instead of the bottom, until the whole is expanded at once. There is something about the flowers that proves a tremendous attraction to the bees, each spike is always swarming with them; but whether this attraction takes the form of nectar or of the pollen masses which are so prominent on the anthers, it is difficult to decide. In common with the rest of its race, the plant loves a sunny position and protection from cold winds, while the soil should be light and rich and freely drained.—CROYDONIA.

THE CELMISIAS.

I AM the happy possessor of a cottage in the back blocks of our New Zealand Southern Alps, in the Canterbury district. It is at an altitude of 2,600ft. In holidays spent there I have almost unique chances of mountain climbing and plant hunting. The neighbouring heights

range to 7,000ft. I have written before of *Raoulia eximia* and *Notothlaspi* (Penwiper plant), both growing in those parts, but there are many other queer plants. One of the most prolific and various is the *Celmisia*, or Mountain Daisy. The smallest has thin, grass-like leaves and a flower about as big as sixpence, and the largest is an erect rosette of broad, sheath-like, silvery grey leaves, with

place where the Edelweiss and *Raoulia eximia* cushions begin, a limit of about 5,000ft.—MARY POULTON, *Shirley, Christchurch, New Zealand*.

CHRISTMAS ROSES.

IN reference to the interesting article on Christmas Roses in the issue of December 23, 1922, it might be mentioned that it is of great importance to get a good strain if specially fine and very white blooms are desired. The writer has three strains in flower at the present moment and one of these

CHRISTMAS ROSES AMONG FERNS.

tall, woolly-stemmed flowers several inches in diameter. Some grow in trails of tight rosettes, forming silvery or green cushions, according to variety. The silvery ones have slender-stemmed flowers, the buds covered in tight hard covers. The green cushions have their buds covered with rough hairy hds, which are really prettier than the full-blown Daisy. All the varieties have white flowers with yellow centres. The leaves are almost always covered underneath with a woolly felt varying from rust colour to white. The young leaves are woolly all over. As they grow older the felt on top changes to a thin silvery skin. The reason given is that, as they are subject to extremes of heat and cold, the felt is useful to absorb water when the ground is frozen too hard for the roots to supply the plants with the necessary amount, and the thin skin is to keep the plants from transpiring too much in the hot summer. I have climbed mountains through acres and acres of Daisies, one variety succeeding another. The slender grassy one, *C. longifolia*, grows in the sub-alpine district for fancy—not necessity like most of them—because it will grow anywhere down to sea-level. This is the lowest grower. Then comes the common Mountain Daisy with flowers about 2ins. across, *C. Traversii*, followed by the huge *C. coriacea*, with its silver leaves and blossoms 4ins. or 5ins. across, not so common. Higher still the trailing cushions of *C. argentea* and the green cushions of, I think, *C. Haastii*; but if anyone would like seed of these, they are welcome if I have any luck collecting next season. It should be a good one, as there was almost no bloom last season, and I will see that the varieties are named rightly. The cushions grow up to the

produces much larger and much whiter flowers than the other two. It was a gift, described as a specially good form and said to be known as *Helleborus niger maximus*. It is certainly larger in every way, including the foliage and the longer flower scapes which hold the blossoms up particularly well. The picture illustrating the article does not appear to be taken from this form, although it is difficult to be certain. The other two kinds, although charming also in their way, do not grow so freely and their flowers have a decided tinge of pink on the exterior. Miss Hope, in a gardening book which does not seem much read nowadays, gives many hints as to propagation and cultivation, and also mentions this fine kind as *Helleborus niger major*, or *maximus* or *grandiflorus*. The article in THE GARDEN, although dealing admirably with the planting, does not mention what appears to be the most important point in their cultivation, especially on dry soils—care of the plants directly after flowering until they have finished making their new foliage. This would consist in giving them a good top-dressing and mulching of well rotted manure or even leaf-mould, with copious waterings, if the weather is at all dry (which it very often is at that time of the year, particularly in the month of May). Amateurs often say they find it difficult to grow and flower Christmas Roses well, and their failure is probably always due to neglect of these attentions. In a very dry autumn, such as the last, an occasional watering will help to lengthen the flower stalks and produce earlier blooms. Christmas Roses are really quite easy to grow satisfactorily, and can be moved and divided at almost any season if attention is paid to watering afterwards. The plant

grows naturally among bushes and, like most semi-woodland plants, dislikes ever getting very dry. Perhaps it never looks so well and happy as when planted among nut bushes, as described by Miss Jekyll; these give the combination of sunshine and shelter from cold winds in spring with the shade from hot summer suns, which exactly suits these delightful winter-flowering plants. A. E. W.

ROSE PINK DELIGHT.

IN reply to "H. G.," this is a beautiful single Rose of the Rambler type. It is a splendid variety, not a rampant grower, usually oft. shoots. With me the colour is deeper than pink, more like carmine and very bright. The trusses of bloom are quite different from the illustration in *THE GARDEN* of December 2. From catalogues I notice it can be had from Messrs. S. McGredy and Son, J. R. Pearson and Sons, Limited, or Mr. J. C. Allgrove.—JOHN MALCOLM.

Our correspondent's enquiry was about a dwarf Polyantha Rose, and the variety mentioned, Laxton's Pink Delight, was, it turned out, the sort which he had been recommended.—ED.]

TWELVE BEST SHRUBS.

I ALSO have been very interested in the lists of the twelve best shrubs published in *THE GARDEN*. I should like to add a list of some which do splendidly here in South-West Sussex. We have a light soil with peat in places, and the shrub garden is well sheltered from the north and east by plantations of Spruce, Larch and Scotch Fir. We are about 500ft. above sea-level. *Grevillea rosmarinifolia*, fine large bush; *Eucryphia pinnatifolia*, roft. high; *Abutilon megapotanicum* (syn. *vexillarium*), this on a wall; *Berberidopsis corallina*, on wall, flowers freely every year; *Eugenia aciculata*, fine bush about 15ft.; *Abelia rupestris*; *Pieris japonica*; *Plagianthus Lyallii*; *Drimys aromatica* and *Winteri*, very fine bushes; *Clethra alnifolia*; *Triacuspida lanceolata* and *dependens*; and *Daphne odora*, on south wall.—RETA HAWKSHAW, *Hollycombe, Sussex*.

A WEEK or two ago one of your correspondents asked for the names of twelve flowering shrubs hardy in Scotland and not near the sea. I give the names of twelve which I have grown successfully for a good many years. I have added a supplementary list which some might care to select from in preference to the first twelve. This is a pretty cold district in winter; we suffer from rime and, in the springtime, late frosts, but flowering shrubs, speaking generally, do well.

The undernoted twelve flowering shrubs I have found hardy, with the exception of *Berberis Darwinii*, which gets cut down in very severe winters, but it should not be omitted. The flowering season is from April till September. *Spiraea arguta*, white, and *Forsythia suspensa* (or *F. intermedia*), yellow, April; *Exochorda macrantha*, white, May; *Berberis Darwinii*, orange, and *B. vulgaris atropurpurea*, fine foliage effect, June; *Weigela rosea*, rose, and *W. Eva Ruthke*, dark crimson, June; *Philadelphus Bonquet Blanc*, double white, and *P. Avonchae*, single white, July; *Euanthus campanulatus*, reddish bell-shaped flowers, foliage good in autumn, and *Deutzia crenata* fl. pl. white, July; *Potentilla Friedrichshagen*, yellow, September. Supplementary list, and all good, *Escallonia* Edinburgh or *Edina*, pink; *P. Philippine*, white; *Enonymus europaeus*, flower poor, but seed pods and foliage fine; *Cydonia pyracna*, flame colour; *Hydrangea paniculata grandiflora*, cream; *Spiraea Anthony Waterer*, crimson.

Large flowering shrubs or small trees, *Prunus pissardi*, pink flower and dark foliage; *Amelanchier canadensis*, white; *Colutea violacea*, yellow flowers,

fine pods. Three good *Rhododendrons*.—Pink Pearl, *Domestic*, dark red; *Corona*, salmon rose. Three *Azaleas*.—Anthony, Koster, Alphonse Lavalée, J. C. Van Tol. Lilaes, *Laburnums* and *Brooms* grow splendidly. *Buddleias*, *Cistuses*, *Veronicas* stand in mild winters.

The following are not hardy in the open garden, at least, to grow and flower well. *Ceanothus*, *Komineya*, *Pittosporum*, *Choisya*, *Desfontainia*, *Eucryphia*, *Viburnum plicatum* and *Ceanothus Gloire de Versailles* do well on a wall. Japanese double-flowering Cherries, both pink and white, do well. Japanese Maples are quite hardy.—ROBT. BROUGH, *Perthshire*.

THE PROPAGATION OF THE HYACINTH.

OF the vast number of people who grow the Hyacinth annually, how many are there who know anything of its increase or, knowing it, have tried the experiment of growing their own bulbs? I think it is well worth trying if only for the added pleasure a genuinely home-grown flower always gives. Those who grow or handle the Hyacinth for sale almost invariably state in their instructions that, having once flowered, the bulbs are of no further use and no doubt this is true of those grown

in natural and artificial increase. The one on the left had its base cut away in the early summer and was laid on a greenhouse shelf. It produced thirty-eight young bulbs, the largest being about 1/2 in. in diameter; the other bulb shows the natural increase. The Dutch growers are said to propagate by means of cuts made partly through the bulb near the base, which is then planted in the open ground, but apparently not much is known here of their methods.—H. C. W.

BUDDLEIA AURICULATA.

IT is a pleasure to see that this useful shrub is mentioned as flowering freely in a Somersetshire garden. Why is it, I wonder, that so fragrant and desirable a plant is so little known or grown? Its creamy white little flowers are so abundant on its leafy and branching growths that it is an ornament to any garden, either in England or on this (the Riviera) coast. Its particular charm, however, is that it "creates an atmosphere of its own," so to say, so pervading, so sweet and so distinct is its fragrance. On these still December days, when yards away from the rough shrubberies where it loves to grow, you say, "How sweet something smells" without having an idea where

HYACINTH PROPAGATION.

in water or fibre, but as regards those grown in good compost this, I think, is hardly correct, for if they can be finished off with the same care as the *Freesias* they will give a good account of themselves in the open ground and will continue to do so for several years. If the grower is of an experimental turn of mind and has the necessary patience, it will be found that the Hyacinth can be increased more quickly than most bulbs. Any bulbs which have been forced and ripened may have the base of the bulb cut clean away and then be laid on a dry shelf. With most bulbs this would be absolutely fatal, but not so with the Hyacinth. The cut will heal quickly and from the base of each scale a varying number of tiny bulbs will be produced according to the amount of nourishment available in the scale on which they feed and grow until nothing is left of the scale but a thin dry skin.

If it is desired to carry the experiment further, the bulblets may be dibbled into pans or boxes of rich open compost and grown on thus for a season, when they will be large enough for a nursery bed in the open. If generously treated they soon reach flowering size. If the first small spikes of bloom are picked off the bulbs gain in strength for the next season. I enclose a photograph of two bulbs showing the great difference

it comes from or what plant it may be. Ten degrees of frost makes no impression on its flowering, so it should be a welcome shrub in many a sea-side garden as well as in the sheltered south-west. It positively thrives on neglect, and is to be found in all the old-fashioned gardens of the Riviera.—E. H. WOODALL.

WILD FLOWERS AT COUNTRY SHOWS.

I READ with interest the remarks of H. C. Ford in *THE GARDEN* for December 2, 1922, questioning the wisdom of the recommendation I made on the subject in the issue for October 21. My intention was certainly not to encourage the wholesale and wanton destruction of rare species of wild flowers, but exactly the reverse. I firmly maintain that the only way to arouse the interest of the rising generation in wild flowers is to encourage them to collect specimens and take them home and have them identified and classified from a good standard work on the subject. The child who is taught to do this will, I am certain, be as anxious as Mr. H. C. Ford, or any other person, not to uproot rare specimens when found, but will long for the season when the same plant will be in bloom again. I am writing from experience and know the joy it has afforded

members of my own family and others to find anything rare and uncommon in the plant world, and how they have revisited the spot where the treasure was found. I have marked, too, their dejection if anything should have happened to mar or destroy what had been a thing of beauty.

My contention is that the more children are encouraged to study nature the more in after life are they likely to appreciate and reverence good, and to pass on the knowledge acquired for the benefit of those who come after them.—HORRIGUS.

NOTES ON TRAPPING VERMIN

(Continued from Vol. LXXXVI, page 660.)

ABOUT the best and quickest way of destroying all underground vermin when their burrows can be found and got at is to use bisulphide of carbon, to be had from any chemist. This most useful substance is both poisonous and highly inflammable, so should be used with caution. It is dangerous to smoke when using it. Search out the rat burrows and carefully stop all holes that can be found except the topmost. Pour into this hole 2 ozs. or 3 ozs. of the liquid and lightly stop the hole for a minute to allow the gas to descend into the lower parts of the burrow. Next remove the stopping from this hole and drop into it a lighted match. The gas will instantly explode and all vermin within reach of the poisonous fumes will be killed. If any holes are accidentally left open, the rats will promptly bolt when the liquid is poured in. Proceed in the same way with the colonies of voles, except that less of the bisulphide is required, as the holes are smaller. Half an ounce will kill the long-tailed mice in their holes, and 1 oz. will settle the largest wasps' nest. As an alternative I can recommend with every confidence McDougall's Vermin Chokers, which will also destroy all vermin in their burrows when used according to instructions given by the makers. The sportsman who has no ferret can use small pieces for bolting rats, using them on the windward side of the burrows so that the fumes will draw through and, of course, no holes must be stopped.

Hawks, owls, stoats and weasels should be encouraged wherever possible. By destroying these the balance of nature is upset, and the result is plagues of vermin, both furred and feathered. Rabbits and hares are very destructive where they gain access to garden and pleasure grounds, but here we are treading on more delicate ground and, generally, great efforts are made to keep them out by fixing wire netting. When fixing this a foot of the wire should be curved outwards in a shallow trench to prevent rabbits from burrowing beneath, which they will do if the bottom is sunk straight down into the ground. The poor man's allotment is their happy feeding ground, and the wire snare is the best way to take them if their runs can be seen, but a lesson on the spot from an old hand is necessary. During the war I was stationed for some time in an Eastern county, and there the allotment holders used an ingenious pitfall constructed with much labour by sinking a deep cask in the ground. The lid was made slightly smaller and balanced at the centre. A bait of Carrots was fixed here and when the animal jumped on the lid it was precipitated into the cask and the lid righted itself again.

Of feathered pests rooks and sparrows are easily scared by placing strands of black carpet thread above or among the seeds or plants attacked. If one rook be shot and hung up on the plot, no other rook will venture near. Most small birds may be scared with streamers of coloured paper, pieces of broken looking-glass, pieces of bright tin or feathers suspended from the top of tall, oblique stakes or from lines. Blackbirds, jays, hawfinches and bullfinches take but little notice of scares, and the best remedy for these is a dose of small shot, but against the first three the gunner must be an early riser.

The large tomtits or oxeyes often do great damage to the later crop of Peas, and their numbers may easily be reduced with the break-back mouse trap. I fix a small piece of wire in the trigger and on it place a green pea for bait, and drill a hole through the trap just behind the spring. Take a fairly stout stake 3 ft. in length, cut the top squarely across, and nail on it a piece of thin board as wide as, and slightly longer, than the trap. Drive a wire nail in the centre, leaving nearly an inch projecting above the board. Cut off the head and pass the spike through the hole in the trap. Three or four of these to a row of Peas will account for a good many tits. It comes as a surprise to many people to learn that these birds eat the Peas. They imagine they are after the small caterpillars in the pod, but this is only partly true. Fasten the trap with a short string tied to a nail near the top of the stake.

Of course, this question of killing birds is always sure to raise a storm of remonstrance from many people, but these kindly souls should consider well the ways of nature to learn the truth about the matter. They will find that this unpleasant duty is forced upon us by the selfish and thoughtless action of those who ruthlessly destroy, in the interests of sport, the raptorial birds and small carnivores, which, if left to do the work for which they seem to have been created, would do the killing for us. The balance of nature would then be kept as it was intended to be.

Lingfield.

H. C. Wood.

THE GARDENER'S FRIEND—THE WEASEL.

SINGLE ROSES

IN the Wichuraiana section there is, I need hardly say, a long list of robust and beautiful hybrid singles well enough known to everyone and adaptable for a wide variety of uses. But there is one Wichuraiana which I would like to mention in particular, and that is the type species, a pure white, yellow-centred creeping Rose which, oddly enough, seeing that most of its progeny are early bloomers, flowers towards the end of summer and continues far into autumn. We grow this delightful thing where it can ramble at will along the ground, intertwining among Heaths and other lowly shrubs on the open spaces of our woodland bank. There is also a variegated Rose whose young shoots are a vivid pink, which appears to be a form of the above. It has the same small white flowers borne in clusters, but it is not nearly so strong a grower as the afore-mentioned. A most delightful little rock garden shrub.

The Ramana Rose (*Rosa rugosa*) is yet another well known species whose immense single, very fragrant blooms in pink, rose, purple and other colours, together with the splendid foliage, make a most effective display for the shrubbery or woodland garden where the plant can spread at will. This good old Rose will do in almost any soil, it does not object to shade, and besides being an almost perpetual bloomer, the big medall-shaped fruits which ripen in late summer remain on the bushes and retain their glowing colour for several months.

Nor can one omit from any list of single Roses, however brief, our own Sweet Briar (*R. rubiginosa*), the "Sweet Eglantine" of the poets and perhaps the most beautiful of all native flowering shrubs. Then we have also the common Dog Rose (one of the parents of the delightful *Una*) the best forms of which are not to be despised in their proper place. *R. arvensis*, the trailing Rose of our hedgerows, whose large, milk white, scentless flowers will open more freely beneath the shade of woodland trees than those of any other Rose I know, is on that account alone worthy of consideration. *R. tomentosa*, common in some districts, is also a very delightful native with its downy foliage and (if you get a good form) rose pink flowers of remarkable purity and depth of tone.

Often classed among the bedders the odd half-dozen of the Irish Elegance set, surpassingly lovely in the warm, rich orange and flesh tints of their broad-petalled flowers, are quite as adaptable for less formal treatment. Jersey Beauty, of the Wichuraiana clan, is a single of exquisite form, opening in a delicate creamy yellow which passes to nankeen—one of the few of its race which may be grown to perfection as a large mounding bush and left to take care of itself. Few Roses have a foliage to equal that of Jersey Beauty, and unless that ravishing creature, Innocence, just introduced to us, has a foliage as fine and a manner as graceful, I doubt whether even her fuller and more radiant charms can wholly eclipse those of the Jersey lady.

To those who would add a glowing butt Rose to their collection of singles there is Mrs. Oakley Fisher, which attracted no little attention at last autumn's shows, while the curiously attractive Queen Alexandra Rose, in deep crimson with a striking buff reverse, somewhat suggestive of a touselled Juliet, will afford an uncommon note of colour. Isobel we all know and love as one of the most exquisite hybrid singles on our lists, and there is the much newer Glowworm, a fiery, refulgent thing for which "Vesuvius" might have been a happier name. It is too soon for us to say how Glowworm is going to behave in our

conditions, but it promises well and has a perfume not to be forgotten. Another excellent new single is Ethel James, as dangerous a rival as Isabel has ever had, but whether this one again will be content to be other than a bedder also remains to be proved.

While no one is more conscious than I am of the omissions from the above paragraphs of many worthy singles in species, hybrids and varieties, enough has been said I hope to inspire those who

have a *penchant* for single Roses to further efforts, and to induce those who have given up bedders in despair to realise what a wide field of possibilities is offered them in another direction. I may add that any of the Roses here mentioned can be planted at any time during winter or early spring in open weather, and that the great majority of them, even the comparatively unknown species, can be secured for about eighteenpence apiece.

North Wales.

A. T. J.

CHARMING DWARF CAMPANULAS

THE opening point of such a note as one that deals with the Campanula for rock and other gardens can scarcely be other than a very big query. Is there a Campanula that is not charming? (I had almost written "indispensable" for charming.) If so, it must be very rare, for I have never yet seen a variety that did not arouse in me the desire to "have a bit" in my garden. This is just where the difficulty comes in; for, while "wanting all," some amount of wise elimination has to be practised or the whole of the space would be occupied by Campanulas to the exclusion of everything else, so numerous are the species and varieties. Selection then is a work of absolute necessity, although one is conscious that the "left outs" are in many cases quite as worthy as the elected. I do not propose to choose either because the variety is rare, or to exclude it because it is common, but upon one count only—its appeal as a charmingly beautiful and good garden plant.

C. Allionii should be planted in a level pocket where it has space to spread, for it is in no sense a crevice lover. Give it a moderately rich sandy loam with plenty of sunshine, so that the roots, which run beneath the surface, have room to push up here and there and form the rosettes of small leaves and large solitary bell-shaped blue flowers that spring from the centre of these. *Allionii* is a native of the South of France and, where failure is experienced, it usually comes from one of two causes—too shaded a position, which means that the soil is not warm enough in spring, or too small a pocket which does not permit sufficient extension of the underground runners. Our native *Hardoll*, in its familiar guise, may become almost epidemic when introduced into the rock garden. I know of few other minute seeded plants that are more capable of taking care of their offspring, but the white variety, *C. rotundifolia alba* and *rotundifolia fl. pl.*, a delightful plant under 1 ft. in height, with tufts of slender stems and a profusion of fully double blue flowers, are never out of place. The white variety is so charming that even if it did become a weed, one would be quite content to pull it up where superfluous and let it go at that. With the double, of course, this trouble does not exist and propagation can only be effected by very careful division of the roots in early spring. Among newer forms, note *C. acutangula*, a trailing blue-flowered plant that is perfect when falling in a cascade over a rock which it covers with its dainty ivy-like foliage.

Close little rosettes of leaves, 2 ins. high, from which, as early as the merry month of May, spring slender erect stems, 6 ins. or 8 ins. high, with lovely wide open star-shaped flowers at the top; this is a description that conveys a very fair idea of *C. alactina*, a beautiful species for prominent pockets that are raised well above ground level. Many find that *C. barbata* is an uncertain and difficult plant, but I have found it do well if one does not expect it to live too long. Most agree that it is perennial and so it may be in some soils, but, for practical

purposes, it is best to regard it as a biennial and sow each year. By treating thus, I have had some really splendid tufts on a sunny rock garden with a westerly aspect. Sometimes the plants do not flower until the second year after sowing and, where this happens, the results are infinitely finer than if flowering takes place earlier. I have seen it suggested that it should be grown in the moraine, but have never tried it in this way, although I am sure that it appreciates a raised position with the sharpest possible drainage and gritty soil, for, if

shape and depth of colour, but the named forms such as Isabel, rich dark violet; *pelviformis*, with its saucer-shaped pale blue bells; *Riverslea*, deep blue; *turbinata pallida*, very pale blue; and *White Star*, a very fine pure white, are infinitely more satisfactory.

"Very fine" is a correct comment on the splendid hybrid variety, *G. F. Wilson*, which is the result of a cross between *carpatia* and *pulla*. It retains the *carpatia* habit and combines with this the rich violet colour of the smaller species and soon makes a large clump covered with flat, salver-like blooms. It will not tolerate shade, but requires full sunshine, combined with a rich, moist, gritty soil. One is sometimes led by circumstances to do things at the wrong time and I plead guilty to having planted *C. garganica* in the middle of the winter, on a Christmas eve to be exact. I was told that this was most certainly among the "doubtfuls," came from Italy and often disappeared in our cold, damp winters. Plants—like humans—sometimes do the unexpected and those specimens, so far from resenting my procedure, grew like weeds and are prosperous and happy to-day, and I would be afraid to say how many years ago it is since I first put them there. A cosy nook is advisable: it is true—and also a well drained,

A TUFT OF CAMPANULA PORTENSCHLAGIANA.

damp lodges round the crown of the rosette of leaves, it quickly succumbs. Drought in summer is equally fatal, so that care must be taken to see that its needs in the way of watering are not overlooked.

C. Balchiana is another kind that appreciates a comfortable home, by which sunshine and a certain measure of protection from cold winds in spring is implied. This may be noted as an unusual trailer after the form of *isophylla*, for the growths trail and the foliage is prettily variegated, while there are masses of pale blue flowers. It is not difficult but I question its entire hardiness and it is safer to take up a plant or two in autumn and keep in a cool greenhouse in winter. Everyone knows the marvellously floriferous qualities of the *carpatia* varieties—good alike in rock garden and border—but I would warn against raising these from seed unless one wishes to experiment. It is interesting certainly, for one gets plenty of variation in size,

slightly elevated spot, but my experience induces me to say "quite hardy." In appearance it is a very effective little plant about 3 ins. high, "neat as a new pin" in habit, with pretty crenulated leaves and sprays of starry blue flowers with a white eye, in addition to which there is the usual alba or white form. Far less common than these is the variety *garganica hirsuta*, a very rampant trailer, differing from the type in that the leaves are densely haired and the flowers light blue, produced from May to September.

Those seeking a crevice lover, should not pass by the variety *haylodgensis*, which is very valuable from many points of view. It is "late" in flowering and at the zenith of its perfection in July and August, a period when good rock plants are worth their weight in gold; it succeeds admirably when packed between two large boulders with the interstice filled with rich gritty loam, for it requires the sharpest possible drainage and exults in warm

sunshine. The habit is prostrate, so that it follows in its growth the form of the cleft in the rocks between which it is growing, smothering itself with masses of pale lavender purple flowers. Writing of "late" varieties reminds me of *C. linifolia* and *linifolia alba*. These, unlike the last-mentioned, are upright growers, with very narrow foliage and thin, wiry stems carrying large cup-shaped blue or white flowers that make a most effective show in August and well on into September. The effect of a single plant is good, but I have determined to find a spot where I can use it in a mass.

A beautiful effect that persists for weeks may be provided by arranging a little "waterfall," but instead of using water, a bed of rich yellow loam should be put down and planted with one of the "wee" *Campanulas*, such as *pulla* or *pusilla*, both of which, when in flower, give such a wild profusion of dainty bell-like blossoms that one has a flower-fall of blue, white or light blue blooms, without being aware of the green foliage that is burned beneath them. This is not a bit of treak gardening. Let each one try it for himself and blame me if not quite captivated by the splendid effect. This does not, of course, exhaust the ways of using these two valuable little varieties, which seem to flourish almost anywhere, for they do well in partial shade as well as in fullest sunlight. If one has a sharp slope well packed with rocks to keep the soil above from slipping, he should try *pusilla* in the chinks and see how admirably it adapts itself to this position, for it will soon "wander" behind the rocks and peep its growths out again in all sorts of unexpected places although it is never rampant nor a nuisance. Another "grow anywhere" species is *C. muralis*, which is more properly listed under the easily remembered title of *Portenschlagiana*, although I confess to having labelled all mine "muralis." This provides a double event, flowering gloriously at two seasons, most considerably choosing two periods when it is especially valuable, *i.e.*, late May when a pause often comes over the garden and again in early October, when anything dwarf and purplish blue has become very scarce. It may be planted in a variety of situations and I think I can promise that it will grow and flower profusely in sun, partial shade or even beneath trees. Small pieces soon spread into wide tufts and it is one of the simplest plants to divide, while for permanent edgings it is beyond criticism. Evergreen in habit, it forms close tufts of crinkled leaves that are bright, restful and refreshing when it is not producing its blaze of blue purple bells. I have seen it described as the "freest blooming alpine *Campanula*," and should think there are few who know it well who would be disposed to contest this. There are two fine varieties of this species, *C. muralis bavarica*, larger and bluer and more vigorous, and major, a new form that I have not seen, but which is said to be finer still. *C. Kaddeana* can be relied upon to give a long succession of bloom from June to October. The flowers are like an open cup of intense purple blue on slender stems 6 ins. to 9 ins. high; a very good variety of spreading growth. Among the hybrids, do not pass *C. Stansfieldii*, for this is a gem, forming dense little tufts of leaves from among which spring stems 3 ins. high, carrying large lilac blue semi-drooping flowers almost all through the summer. It is a good variety to spread quickly and loves a deep pocket in an open position. Quite distinct is *C. nitida*, a delightful little miniature with dark shining evergreen leathery foliage, from among which rise erect stems bearing whorls of rather large flat blue flowers from July to September.

And so one might continue remarking upon variety after variety until a complete list had been made, but time has come to call a halt and I will conclude with *C. Steveni nana*, a dwarf and

compact form of *Steveni* which makes a perfect carpet of narrow light green foliage, above which, at a height of about 4 ins., are large lilac

blue flowers in July and August, the dainty little blooms nodding on the stems with every breath that blows. H. W. CANNING-WRIGHT.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

The Seed Order.—If not already done, no time should be lost in despatching the seed order, for although the bulk of the seeds will be sown later, it is time a start was made with some of the early vegetables.

General Work. Every opportunity should be taken to get manure on the ground, also any ashes from the rubbish fire, and old potting soil if there is no other use for it. Such crops as Onions, the Cabbage family, Leeks, Beans and Peas enjoy a liberal dressing of manure. If the ground is in good heart, no manure will be necessary for Carrots, Parsnips, Potatoes and Beet, but a sprinkling of some fertiliser may be given at the time of planting.

Dwarf Peas.—For early supplies a sheltered south border should be chosen, and the kinds I have found successful are Langley Gem and Pioneer. Select a fine dry day and plant 3 ins. deep in drills 2 ft. apart.

The Flower Garden.

Herbaceous Borders.—At an early date these borders should be given attention, the old growths cut down, and large stools of *Michaelmas Daisies*, *Heleniums*, etc., may be lifted, divided and the outside pieces replanted. *Peonies*, *Delphiniums* and *Phloxes* are best left alone for two or three years. The border can be dug over and well decayed manure incorporated as the operation proceeds. If new borders are contemplated, the ground should be trenched and manured a week or two before planting takes place.

Roses.—When the soil and weather are favourable the planting of *Roses* may be completed, although much work can be continued until March. Deep planting must be avoided, and standard trees should be secured to a firm stake.

Gravel Paths. Where new gravel is required it may be applied at this season, and if it is rolled occasionally a smooth surface will be obtained before dry weather sets in.

The Rock Garden.—This interesting section must be examined and a sharp look-out kept for slugs, which are numerous in some gardens. Traps are useful, and many of these pests can be collected and destroyed in the early part of the day. Tender plants will need protection during severe weather, and sheets of glass, conifer boughs, etc., will be found suitable, but they must be removed directly the weather improves. The soil can be lightly forked over and, where needed, a top-dressing of gritty soil given. A note ought to be made of any failures and the plants replaced any time before March.

Fruit Under Glass.

Peaches.—In some gardens will be found two or three Peach-houses, and where such is the case the earliest trees will have started into growth and be approaching the flowering stage. When the flowers are open they will need to be fertilised artificially, and a rabbit's tail tied on the end of a bamboo cane is usually chosen for this work. Select a fine sunny day and then touch the flowers lightly with the tail. Maintain a temperature of 60° to 65° by day and 55° at night, and ventilate the house whenever the weather is mild. Watch for green and black fly and lightly fumigate the house directly these pests are seen. In the later houses the pruning and cleaning of the trees and washing down the woodwork and glass will need attention. When pruning the trees cut out the wood that has borne fruit during the past year and tie in the young shoots which will bear fruit this season. Care must be taken to avoid overcrowding, for this and overcropping is a failing not only of amateurs but occasionally of professional gardeners. If any new trees are required in the late house, they should be planted at once. When selecting varieties that known as *Alexandra Noblesse* ought to be included, as its flavour is excellent.

The Hardy Fruit Garden.

Planting Fruit Trees.—Where it is intended to replace old trees or useless varieties with better kinds, such work must be completed without further delay. Standard trees will need to be made quite secure to a stake, and each tree should be examined occasionally to ascertain if it is

still firmly embedded in the soil. All stone fruits enjoy lime in some form, and when planting such trees sprinkle a little wood-ash and mortar rubble among the roots. All damaged roots should be carefully cut off with a sharp knife and the very strong ones cut back slightly in order to encourage the formation of fibrous roots, which are so beneficial to the tree. Specimens planted against a wall must not be tied permanently until such times as the soil has settled down.

Manure for Fruit Trees.—Plantations of Currants, Gooseberries and Raspberries will be greatly assisted by a liberal dressing of good farm-yard manure, and it should be applied as soon as possible or during a spell of frosty weather. The ashes from the garden fire may also be used with advantage.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),

Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Seed Order.—The seed lists are now to hand, and it will be in the interests alike of the vendor and purchaser if orders are placed early. The making up of the list of vegetable seeds is a comparatively easy matter for those who have had previous experience. The quantities are pretty well known, and a written or mental note will have been made of varieties which have proved satisfactory or otherwise. Notwithstanding disappointments in the past, a few novelties should be included; but for the bulk of the supply reliance should be placed on well tried varieties. The selection of flower seeds calls for greater forethought, as planting schemes are varied more or less year by year. Plans for the coming season should be more or less definitely fixed now, as it is bad policy to order seeds haphazard.

The Kitchen Garden.

Digging and Trenching. Have the digging or trenching of all vacant quarters completed as soon as possible, so that the soil may get weathered before cropping operations commence.

Rhubarb.—With the advent of the New Year Rhubarb crowns will be more easily excited into growth for early supplies. Various devices may be employed. A good torkful of rather dry, loose litter or leaves may be lightly placed on the crowns, or they may be covered with extra large flower-pots or a circle of corrugated iron placed over them.

Seed Potatoes.—If not already done, "seed" of early varieties should be packed closely together in wooden trays, crown upwards, and placed in a light position where a temperature of 40° to 45° can be maintained.

The Hardy Fruit Garden.

Combating Caterpillars.—Gooseberry bushes are subject to attacks by caterpillars of two kinds: those of the magpie moth and the sawfly. Both pests may be dealt with during the spring or summer, but "prevention is better than cure," so if their presence is suspected they should be taken in hand now. The sawfly caterpillar deposits its eggs in the soil under the bushes where it has been lodging. A heavy dressing of lime or soot generally proves effective for these. Rake the dressing lightly in. The magpie moth caterpillar is more beautiful, more destructive and more difficult to destroy. It deposits its eggs on the gossamer-like threads it suspends on the branches of the bushes. A good spraying with arsenate of lead at the rate of 1 lb. to a gallon of water, plus a little treacle to make it sticky, is almost sure to make short work of this pest.

Pruning.—The pruning of all kinds of hardy fruit trees should be completed as quickly as possible, as the sap will soon be on the move upwards again. Pruning should not be carried out during frosty weather.

Fruit Under Glass.

Mid-Season Vines.—In houses where ripe Grapes are required early in August preparations should be made now for starting the Vines. Pruning will have been attended to, so the work at the present will consist of thoroughly washing down the woodwork and glass with soap (no soda) and moderately warm water, removing all loose bark

from the Vines and giving them a dressing with Gishurst's Compound, working it well into the crevices of the spurs. Limewash the walls with hot lime and remove some gins, of soil from the surface of the border and replace it with maiden loam, plus a little lime, wood-ashes and bone-flour. Water the border if dry.

The Flower Garden.

Digging and Trenching.—All vacant ground should be trenched or dug as soon as possible. Ground that is to be occupied by annuals may be allowed to pass with a light dressing of manure and single digging, but that intended for the reception of Hollyhocks, Dahlias, Pentstemons or Chrysanthemums should receive a liberal dressing of manure and be either trenched or double dug.

Sweet Peas.—Those who desire to obtain long-stemmed Sweet Peas with plenty of "fours" must lay a good foundation on which to build their hopes. A trench should be taken out about 2ft. wide and 2½ft. deep. The trench should then be filled up to within a few inches of the ground-level by mixing the top spit of the excavated soil with turfy maiden loam, half-decayed vegetable refuse or the contents of pots in which Chrysanthemums have been grown, adding to the mixture some bone-flour or bone-meal. It is not advisable to apply quick-acting fertilisers at this stage, for if this is done it is very apt to induce the dreaded streak. Plants treated as advised above will require supports at least 5ft. high, and these should be seen to now. Those who can secure them cannot do better than use natural stakes—branches of Beech, Elm or Hazel being most suitable for this purpose.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mans, Midlothian).

GREENHOUSE AND CONSERVATORY.

Greenhouse Climbers from Seed. There are quite a number of climbers of a more or less annual character that can be raised from seed sown early in the new year. It is wise, therefore, to procure a supply of seed as soon as possible. One of the most striking and possibly the least grown of all is *Rhodochiton volubile* with pale reddish

calyces and dark blood red tubular corolla. If grown on in sin. pots it will make growth some 10ft. in length, and will flower freely all through the latter part of summer, autumn and even during the winter months. This plant is really a short-lived perennial, and is very fine in its second year if it can be planted out and trained on a rafter or to wires under the roof glass. Usually it is not worth keeping after the second year from seed. Other climbing plants that may be treated as annuals are *Cobaea scandens*, *Ipomoea rubro-coccinea*, *L. coccinea*, *Mimosa lobata*, *Thunbergia alata* in several colours, *Eccremocarpus scaber* and *Maurandia Barclayana*. There are some six species of *Maurandia*, but *M. Barclayana* and *M. scandens* (*Lophospermum scandens*) are the two most commonly seen in cultivation. The majority of the plants mentioned are half-hardy, and in the South at least may be planted out and trained against walls or trellises during the summer months.

Asparagus Sprengeri and *A. plumosus* and its variety *nanus* are more or less indispensable in most gardens. As the seeds take some time to germinate and the plants in their younger state are somewhat slow-growing, seed should now be sown as soon as possible, soaking the seeds for twelve hours in warm water before sowing. The seed-pots should then be plunged in a case with bottom-heat, covering the pots with a piece of glass until germination takes place. *A. Sprengeri* makes an excellent basket plant for the conservatory. The plants are very beautiful when covered with their small white, starry-shaped flowers, which usually set plenty of fruits, the latter being bright red when ripe.

Asparagus decumbens is a very graceful and dainty species for hanging baskets, and it is surprising it is not more generally grown, as it succeeds perfectly well under the same conditions as *A. Sprengeri*. *A. scandens deflexus* is also a very beautiful species of somewhat the same habit. *A. medeoloides* (Smilax) and its variety *myrtifolius* are usually in great demand for decorative work, and where wanted for this purpose seed should be sown early in the New Year. Grown on into 6in. pots and trained round several slender stakes they are useful for furnishing the stages in the greenhouse or conservatory, but if required for a supply of cut shoots they should be planted

out and each shoot allowed to run up a thin string. The back wall of a greenhouse is a suitable place for growing them. Failing this they may be planted against and trained up the back walls of vineries. *A. retrofractus* is a very distinct and beautiful species, which is seen at its best when planted out and trained up a pillar in a cool house.

Manettia bicolor is a very old garden plant, but does not appear to be very common in gardens at present. It is a twining plant, with small, tubular scarlet flowers tipped with yellow, and has the merit of being more or less in flower all the year round; but is useful, as it flowers during the winter months. It can be planted out and trained up a pillar; but nice plants can be grown in 6in. pots, training the shoots round neat stakes. It is easily propagated by means of cuttings inserted in pots of sandy soil and stood in a close case. The plant grows quite well in any ordinary potting compost, and while growing should have warm greenhouse treatment.

Royal Botanic Gardens, Kew.

Answers to Correspondents

TREES AND SHRUBS.

TRANSPLANTING ROMNEYA COULTERI (W. M.).—Transplanting the tree Poppy is a risky operation, especially if the plant is a large one. It is not so much a question of climate as of soil and position. In a sheltered sunny position and a well drained loam, *Romneya Coulteri* should succeed in Gloucestershire. The positions to avoid are damp, cold places and heavy soils. This is not a favourable time for transplanting; spring is the best season. As our correspondent apparently has no alternative, it is worth while taking the risk with a plant so delightful when it succeeds. Plant a portion in the flowering position and put up some of the smaller pieces, placing in a cool greenhouse. Growth is sometimes slow for the first year, but once established the plants grow and flower freely. Do not plant the crowns deeply, rather protect with bracken, dry leaves or litter in severe weather. In lifting it would be much better to save all the fleshy roots possible, the broken ends have an unfortunate habit of dying back. If the transplanting proves a failure, raise young plants from seeds.

NAMES OF PLANTS.—"Lanrick."—1. *Centradenia rosea*; 2. *Polypodium aureum*; 3. *Chlorophytum elatum variegatum*; 4. *Veronica Lyallii*.

NAME OF FRUIT.—C. F. T. W., Suffolk.—Apple striped Beeching.

SEWAGE DISPOSAL FOR COUNTRY HOUSES.—No emptying of cesspools; a perfect fertiliser; no solids; no open filters; perfectly automatic; everything underground. State particulars.—**WILLIAM BEATTIE**, 8, Lower Grosvenor Place, Westminster.

IRON AND WIRE FENCING for Gardens,
Tree Guards, Gates, Arches, Espallers, Rose Stakes and Ornamental Garden Iron and Wirework of every description. Send for Illustrated Catalogue. Also Kennel Railing and Poultry Fencing. Ask for separate lists.—**BOULTON AND PAUL, LIMITED** Norwich.

ROCKERY PLANTS SPECIALITY.—List free.
TERRY LEE, F.R.H.S., 16, Morden Rd., Stechford, Birmingham.

SUTTON'S VEGETABLE SEEDS.

By constant selection and re-selection year by year, our choice strains are maintained at the highest standard of excellence. Our speciality for the week:

PEA, SUTTON'S EARLY GIANT
Pods large, very handsome and produced in great profusion; flavour superb.
Per pint, 2s. 6d.; quart, 4s. 6d.

SUTTON & SONS, THE KING'S SEEDSMEN, READING

NOW IS THE TIME TO PLANT
KELWAY'S LOVELY PÆONIES and the **KELWAY COLOUR BORDERS**, which include our world-famous Delphiniums, Pyrethrums, Lupines, Gaillardias, Phloxes, Pæonies, etc. Fine collection of Flowering Shrubs and Roses now ready.—Write for descriptive Catalogues to **KELWAY AND SON**, The Royal Horticulturists, Langport, Somerset.

DOBBIE & CO., LTD., Royal Seedsmen, **EDINBURGH**, will send a copy of their 1923 Catalogue and Guide to Gardening, free, if this paper is mentioned.

BATH'S HOME GROWN BULBS.—New Illustrated Catalogue of the finest Narcissi, Hyacinths, Tulips, etc., as supplied to the Royal Parks and Gardens, with full cultural directions, is now ready, and will be sent post free on application.—(Dept. E), **R. H. BATH, LIMITED**, The Floral Farms, Wisbech.

BATH'S SELECT SEEDS AND PLANTS.—New Illustrated Catalogue of Choice Vegetable and Flower Seeds and Plants is now ready, and will be sent post free on application. Special terms to Allotment Societies.—(Dept. E) **R. H. BATH, LTD.**, The Floral Farms, Wisbech.

BIRDS' BATHS, GARDEN VASES, SUN-DIALS, NESTING BOXES. Catalogue (No. 4) free.—**MOORTON**, 65, Pearl Road, Walthamstow.

PRIOR'S COLCHESTER ROSES, Fruit Trees, Shrubs, Gladioli, Dahlias, Alpines, Carnations, Herbaceous. Catalogue containing cheap collections free.—**D. PRIOR & SON, LTD.**, Colchester.

CHOICE NEW CHRYSANTHEMUMS. Our New Catalogue of over 700 varieties, including 50 Novelties for 1923; also including finest Dahlias, Pelargoniums, etc., is now ready, post free on application.—**J. W. COLE & SON**, Chrysanthemum Nurseries, Peterborough.

DOWNER'S NEW RED LUPIN, 10 6 each.
Apply for List.—**DOWNER** (Dept. 2), Drayton Manor Nurseries, Chichester.

WIRE BARGAIN! New Government Surplus!
Ideal for training peas, beans, hops, tomatoes, small trees, wiring greenhouses, tying, fencing, etc. Waterproof, flexible, steel stranded and long lasting. Cash price, 19 6 per mile (full 1,760 yards). Send for trial lot or samples to-day.—**GREEN'S SURPLUS STORES**, 205, Seymour Road, Lytham.

PRIVET & THORN.—Also Rhododendrons, Heathers and Alpines. Send for List.—**HODSONS LIMITED**, 58, Castlegate, Nottingham.

ECONOMY IN THE GARDEN.—Our illustrated List, containing a Selection of the best Vegetable and choicest strains of Flower Seeds at strictly moderate prices, is now ready and will be sent free on application.—**J. R. PEARSON & SONS, LTD.**, Loddham, Notts.

SHOW AND REGAL PELARGONIUMS.—Strong, clean, healthy plants from 3in. pots. 12 fine named varieties, 7 6. Newer ones, 10/- and 12/- per dozen. Novelties of 1920, 15/- per dozen. All free by parcels post for cash with order, or cart. paid per passenger train in Leatherboard pots, 2 6 per dozen extra. Catalogues extra.—**J. W. COLE & SON**, Midland Road Nursery, Peterborough.

GREENHOUSE PAINTING AND GLAZING.
—"Vitrolite," superior to White Lead Paint, 18 6 per gallon, cans extra. "Plastice," the Imperishable Putty, 32/- per cwt.; kegs extra; 7lb. tins, 4 3, post free; 14lb. tins, 5 6 each, carriage extra, tins free.—Full particulars from **W. CARSON AND SONS**, Grove Works, Battersea

SUTTON'S

Record Improvements in GARDEN PEAS

Could the history of the evolution of the Garden Pea be written it would afford a story of unusual interest. At one time the varieties available scarcely exceeded a dozen in number, and these produced peas of a quality which would now be considered only fit for boiling in a dry state. But in the hands of experts such wonderful improvements have been achieved that the high-class Peas of the present day resemble their progenitors in hardly any one characteristic. Not less remarkable than the attainment of superb table quality is the extraordinary development in the size of the pods and the peas in them. Our well-known Pea, The V.C., is the largest-podded variety in cultivation, and customers have grown magnificent pods up to nine inches in length. The duration of the Pea crop has also been greatly extended, and by growing suitable varieties it is now possible to obtain supplies from the open ground from May to November.

[JANUARY 13, 1923.]

GENTIANAS, DWARF AND TALL

Their Value and Culture.

LAST week we considered very briefly some of the most useful plants belonging to the Borage Order—an Order remarkable for the admirable blue-flowered plants it contributes to the garden. This week we purpose passing in review some of the more effective species and varieties of the Gentian family, which provides us with the richest and most velvety blues any flower affords.

It is rather astonishing that to many gardeners the name Gentian brings to mind little else than the great Gentianella, which they call (or miscall) *Gentiana acaulis*. The beauty of this plant no one can gainsay, but it has no right to monopolise to itself the glory of all the Gentians. The gardener who can grow the Gentianella, or rather who succeeds with it, is apt to be a little tolerant of those less fortunate in this respect. This Gentian is certainly a whimsical plant. It misled even the late Reginald Farrer, who seriously recommends to grow it in deeply worked kitchen-garden soil, with an abundance of lime rubble. He lays stress upon the last mentioned ingredient. Now the writer has grown this plant in light, hungry soil, destitute of lime and it spread into and flourished in the gravel path. It would seem then that it is a very accommodating plant. Failure to grow almost always indicates impure air, due to the proximity of a manufacturing area. Failure to flower may be due to too rich soil, but often means only that a poor strain has been obtained. The Gentianella, though probably of hybrid origin, reproduces itself fairly true from seeds, but unquestionably some of the seedlings are as shy to bloom as others are free. There are, besides colour forms, several named varieties in commerce and some have extra large flowers. Freedom to blossom, however, is more important than size of pip and

gardeners who cannot flower the plant well would be well advised to try several different stocks in the hope of improving matters.

Linnaeus's *Gentiana acaulis* covers a number of somewhat dissimilar species, as well as the *Gentianella*. *G. vulgaris* is usually met with in gardens as *G. Clusii*. It has very handsome upstanding trumpets of a glorious azure blue. In cultivation it is not difficult in a well drained limy soil or, preferably, in the limestone moraine. *G. latifolia* on the other hand is the peat-loving *G. Kochiana* of gardens. The colour of the species is variable, but is generally dull and not seldom muddy. It is easily recognised by the rather large and distinctly floppy yellowish foliage. *G. angustifolia* may easily be distinguished by its long narrow bright green leaves. The whole plant is taller than we should expect in the *acaulis* kindred and the flowers, though not large, are a beautiful blue. The limestone moraine is the best place for it when it can be obtained. *G. excisa*, which is nearest to the *Gentianella* of gardens, is a comparatively rare species in the Alps and rarely offered by the trade. It has ample very dark green glossy foliage and stout comparatively tall

flower stems and, above all, wide mouthed trumpets of a glorious blue. In a light gravelly loam this is not a difficult species to establish if plants can be procured. Others of the *acaulis* kindred are *G. G. dinarica* and *occidentalis*, both beautiful in their native mountains, but hardly likely to be procured unless, perchance, from seed.

Practically every lover of alpine plants has tried *G. verna*. Many can keep it alive for a year or so; comparatively few really succeed with it. It seems to like a rather light gritty compost with an admixture of peat or leaf-mould. It certainly likes the company of other plants. It will even struggle with and hold its own against the rampant *Campanula Portenschlagiana*! but smaller growers are abundant. *Saxifraga oppositifolia* is a very suitable companion, so are some of the small *Alyssums*. The plant's great enemy in our lowland gardens is winter wet, which accounts for its comparative ease of culture in the alpine house.

Of the other small Gentians of the European Alps, *G. bavarica* is perhaps the most lovely in its intensely dark velvety flowers. The foliage is yellowish and the flower stems taller than those of *G. verna*. It needs bog conditions in summer, but not in winter. If these can be provided in gritty, peaty soil, it is not really difficult either to establish or to flower. It is, naturally, easier in pans in the alpine house than in the open rock garden. *G. brachyphylla*, which replaces *G. verna* at the high levels, is more compact than that species and there is a distinctly glaucous look about the foliage. It flowers in July and, strangely enough, many gardeners find it an easier plant to establish than *G. verna*. *G. imbricata* which replaces *G. bavarica* at higher altitudes is a miniature of that beautiful species, but exceedingly difficult to grow, even in the alpine house. From the Roof of the

GLORIOUS BLUE TRUMPETS OF THE GENTIANELLA.

Willow are a very distinct set of alpine Gentians which are now becoming common in the better collections of species. Of these *G. Freyniana* and *G. septemloba* are the best examples. Farrer writes of it: "As soon as *G. Freyniana* coming into bloom in mid-September on all the high alpine sword of the Da Lungshan (Northern Kansu Tibet), it is by far the most astonishingly beautiful of its race, reducing *G. verna* and *G. Gentianella* to the dimmest acolyte." As we grow it in Britain it certainly does not compare for splendour with either of the species named. To begin with the fine light green foliage, perhaps more beautiful in itself than the still green tufts of the *Gentianella*, seems a less satisfactory background for the azure trumpets. Again, the fierce luminous Cambridge blue which Farrer described probably less "nerve" in cultivation lacks the velvety depth of *G. Gentianella*. None the less this is a magnificent autumn-flowering species—the quaint striping of the buds reminds one of an *Ipomoea*. Outdoors it likes a gritty but moist cool soil. It is grown to perfection in the rock garden at the Royal Botanic Garden, Edinburgh, and as at least one firm in the trade holds an immense stock of it, it is readily procurable. *G. sinuornata*, which is an equally easy doer, is very similar in general appearance even to the striping of the outside of the flower. It is none the less quite distinct. This also is an autumn-flowering species. *G. Kurroo*, which, at long last, received a few months ago the R.H.S. award of merit, is seen to much greater advantage on a shelving ledge in the rock garden than in a pot on the exhibition table. From a central, multiplying tuft of long narrow strap-like leaves one or two flower stems radiate in late summer. These are, at first, horizontal, but they ultimately sweep gracefully upward to display the large trumpets of a rich gentian blue, lighter in the throat. It is easily understood that with its stems gathered up to stakes for security, a potted plant loses much of its grace and individuality. In the garden, *G. Kurroo* likes a hot exposure, but not drought. As it is inconvenient to supply water underground all over the rock garden, this usually means a site in a sun-kissed corner of the moraine.

Now without bothering about any more Asiatic high alpinists, let us consider awhile the taller-growing lowland species. First of all we have the Willow Gentian, *G. asclepiadea*, which makes a poor picture in black and white, but is, when well grown, undoubtedly lovely, with long bending sheaves of sapphire blossom. It likes a deep, cool soil, but does not seem greatly to trouble whether this be light or heavy. Like most of its kindred, the Willow Gentian is very variable as regards blossom colour. Some of the drab-coloured varieties in commerce are quite unworthy of cultivation.

G. septemloba obviously belongs to the same section as the Willow Gentian, but is a dwarter grower. The 6 in. long stems are fragile, and look more fragile than they are. The soft blue flowers are much larger and more widely expanded than in *G. asclepiadea*. This is an easy plant to establish in a cool corner in soil containing abundance of lime. *G. Lagodechiana* illustrated is practically identical with the equally easy to grow and wonderfully beautiful *G. Freyniana* is also closely related to *septemloba*, but dwarter, and quite distinct in external appearance. *G. Androsii* is another plant belonging to the section, and a very easy doer. It is heavier and more botanically than *septemloba*.

G. Pannoniensis is a British native, and to that fact better worth cultivating than some of the cowardly species from far off land. Not that *G. Pannoniensis* can properly be described as cowardly, though it is not a particularly showy plant. The exterior of the trumpet-shaped blossoms, which in

THE TRAILING SOFT BLUE FLOWERS OF GENTIANA LAGODECHIANA.

MASSSES OF GENTIANA FREYNIANA.

AZURE BLOSSOMS OF GENTIANA SINO-ORNATA.

the garden is the more noticeable), is a dull greenish blue, but the interior colouring is rich and velvety. The best form, a foreign one, is known as *G. P. arvensis*, but there is also a very attractive albino. Closely related is the little dwarf *G. glauca*, with grey foliage and green and blue blossoms. *G. linearis* again is a New World species also belonging to this section growing 1½ ft. tall with small clustered heads of whitish blossoms—not one of the most attractive species though well enough in its way.

To quite another section belongs the stalwart yellow Gentian of the alpine meadows—*G. lutea*. The plant is of economic importance, for to its root we owe one of the best and most harmless stomach tonics known. It should have a deep and rich but open soil and be grown in groups rather than as single specimens, when the handsome corrugated foliage and starry golden flowers are really effective. None of the others of this section is worth growing.

A REMARKABLE SAXIFRAGE

THE late Reginald Farrer was much more of a collector of plants from the wild than a plant breeder and hybridist, and as a collector he had an extraordinary eye for special forms and varieties. But he writes amusingly in his books of certain crosses which he made among Saxifrages and of his rather haphazard methods in not recording the parentage of these crosses. Yet he achieved one hybrid at least of first-class importance in *Saxifraga Mira*. We all remember what a flutter went round when the charming little *S. Irvingii* made its appearance at Kew, the first pink hybrid from *S. Burseriana*. I saw a picture and an account of it in *THE GARDEN* one morning, and caught the next train to Kew to pay my respects to it. *S. Irvingii* will always remain a first-class plant; it is so neat and thrifty, so good a grower and so free to flower. Moreover, its flowers are a pure delicate pale shell pink. But *Irvingii* having made the stir it did, imagine my feelings when I came upon a hybrid of the same persuasion as *Irvingii*, but with slightly larger flowers of a bright rich cherry red—the colour almost of *Potentilla Willmottiae*. I was paying a hurried passing visit to Farrer's Craven Nursery. Farrer was away on his last fatal expedition. In one of the nursery frames among a lot of odd mixed treasures were eight or nine little pot plants of this wonderful new hybrid in full flower. I could hardly believe my eyes, and the picture of those astonishing little plants haunted the back of my mind for days after. Farrer had named the plant *Mira*, but I have never been able to discover for certain what was its parentage. Rather more than a year later, after Farrer's death, I received through the kindness of Mrs. Farrer the major portion of the stock, and on flowering it here I find that there are two distinct forms, one of which is a much darker richer red than the other. The lighter form has been shewn and received the R.H.S. award of merit, and there has been enough of it for distribution. Of the darker better form there was very little, and at present it is unshewn and unpublished. The two forms are identical except in the matter of colour, but in colour they are very distinct, and the darker form will have to have some distinguishing name. *S. Mira* is a slow grower, but of sound, reliable constitution. It is close and hard and compact in growth, larger in the rosette than *Irvingii*; broader, blunter and greener in the leaf, and larger in the flower.

Stevenage.

CLARENCE ELLIOTT.

THE BEST VARIETIES OF HOLLY

THE Holly is a singularly useful tree, since it provides the strongest of boundary hedges and one that will grow beneath the shade of trees where the Quickthorn, for instance, would fail. It is invaluable, too, for undergrowth—it will grow, if the ground be properly prepared, under Scots Pines and other conifers. Many varieties of the Common Holly (*Ilex Aquifolium*) and some of the species make exceedingly handsome specimens, with rich glossy foliage. The beauty of the female Common Holly when wreathed in brilliant berries needs no commendation. Even the derelicts of our London slums are familiar with the leaf and berry of Holly.

The handsomest of green varieties of the Common Holly is called *camelliaefolia*. The dark glossy leaves are sometimes 5 ins. long, but relatively

as variety *atlanticensis*. *Wilsoni* is another huge-leaved variety—and female.

The variety known as *scotica* might almost be called a smaller-leaved edition of *camelliaefolia*. Spined leaves are even less frequent upon this variety than upon the last mentioned. Another remarkable, almost spineless variety is that called the *Dominington Holly* (variety *domingtonensis*), which has narrow, oblong, purplish leaves and purple bark. This is a male variety, but very handsome. Variety *Smithii* is similar but less effective, as it lacks the purple bark and purplish foliage.

Very distinct is the form called *latispina*, also with purple bark and with very long and slender spines. *Monstrosa* has similar long slender spines, but more of them, frequently eight to ten to each

THE WEEPING FORM OF THE COMMON HOLLY, *ILEX AQUIFOLIUM PENDULA*.

narrow and are, for the most part, spineless, though some have a few spines towards the tips. This form makes an attractive columnar tree. It is female, but does not berry at all freely.

The variety *Hodginsii* has leaves much larger and darker than those of the typical plant, also shorter in their proportioning. The individual leaves are glossy, but there is something "dead" in the gloss, so that the tree, as a whole, lacks the "finish" of *camelliaefolia*. This is a female variety and berries freely. It is much confused in nurseries with the variety *Shepherdii*, which has leaves similar in form and probably larger on the average, but brighter in colouring.

A weeping form of the Common Holly is not uncommon in hedgerows. Such weeping plants may be either male or female, but the form stocked in nurseries as variety *pendula* is a beautiful weeping form which berries freely. This Holly is much admired by many people who do not ordinarily care for weeping trees. There are silver and golden forms of this Weeping Holly, the former usually listed as *Perry's Weeping* and the latter as *amea pendula*.

A fine large-leaved male Holly with purplish bark is known as the *Highclere Holly* or (*latinised*)

leaf. The Hedgehog Holly (var. *ferox*), is another variety with purple bark. Leaves are on the small side and crumpled. Besides the marginal spines of the Common form, there are clusters of short spines on the upper surface of the leaf. This is a male variety. There are forms of this curious variety with leaves variegated with silver and gold respectively. The silver form seems permanent enough, but the gold one has a tendency to revert to the green hedgehog form. All three are, perhaps, more curious than beautiful. Two other "freak" varieties are called *crispa* and *crassifolia*. The former has its leaves, which have, as a rule, few spines, spirally twisted. *Crassifolia*—often called the *Leather-leaved Holly*—has shoots and foliage curiously thickened and succulent in appearance. The young shoots are purple. Neither of these forms has any particular beauty.

The variegated forms of the Common Holly are interesting and some of them really beautiful, but like most variegated plants they are easily "overdone" in the garden. The two handsomest of these coloured forms are probably *Golden Queen* and *Silver Queen*, especially the latter. Both, oddly enough, are male varieties. In both, the variegation is clearly marked, bright in colour and

broad. Of the white-margined Hollies, Hands-worth New Silver is probably the most handsome. Like most of the silver-margined sort—it is female—and fruits moderately well.

The Silver and Golden "Milkmaids" have heavy central bands of colour surrounded by an irregular green margin. They are much favoured in some gardens. Male and female plants of either are pronounced. Waterer's Holly is a dwarf, compact sort, very dense in habit and its foliage scarcely spiny. The latter is very dark green, sharply margined rather bronzy gold.

There are great numbers of species of *Ilex*, of which perhaps the best known is *I. crenata*, though the Canary Island Holly, *I. platyphylla* is no doubt partly responsible for many of the so-called forms of *I. Aquifolium* already described. The leaves are much larger than those of our own species and the gloss on the foliage seems shallower and less translucent. The sub-species *balearica* has smaller foliage than the type and, as grown, is usually, perhaps always—female. It is almost certainly harder than the typical plant, but not very hardy at that. It is worth noting that even the Common Holly is not among the hardiest of plants. Young, immature wood is often cut by frost and in very severe winters, such as, happily, few of this generation have experienced, is sometimes killed outright. Nearly related to the Balearic form is the variety *madeirensis*, with brighter foliage.

Ilex crenata is the Japanese Holly, with leaves seldom exceeding 3 in. in length. It grows into a shrub 3 ft. or 4 ft. tall and might easily be taken at a little distance for a small-leaved *Osmanthus*. The form known as *major* attains, in time, the stature of a small tree and has rather larger leaves. This probably is the typical form of the species, the specific form as we know it being a form selected by the Japanese, whose fondness for dwarf shrubs is notorious. However this may be there is a form much smaller even than the one English botanists regard as typical. This is called *Mariesii*, of which the growth is extraordinarily slow and congested. It is, therefore, quite a useful shrub for the rock garden. The Japanese Holly has black fruits. *Ilex Pernyi* is another small-leaved species, ultimately attaining the dimensions of a small tree. The foliage is not unlike that of our English Holly, very much reduced in size and the fruits are red.

Ilex opaca is the American Holly. It also is red fruited but, compared with our native tree, has little beauty. The Himalayan Holly, *I. dipetala*, is oddly enough somewhat similar. This also is undoubtedly nearer to *I. Aquifolium* in beauty.

For our western shores there is the remarkable *I. insignis*. The oblong leaves are of immense size—up to 6 ins. long, dark green with a

prominent pale green mid-rib. It has bright red fruits. *I. integra*, known in gardens as *Othera japonica*, is remarkable as a large-leaved entirely spineless Holly. The fruits, which are bright red, are remarkable for their size—3 in. in diameter. It should be hardy in any but very bleak localities. *I. latifolia* from Japan, is an exceedingly handsome

species with huge lustrous green leaves and large bright red fruits, abundantly produced. It is, unfortunately, hardy only in the south. There are several other evergreen species and a number of deciduous ones which were formerly called *Prinos*. They do not agree with an Englishman's idea of Holly and need not be mentioned here.

PLANTS FOR THE PATHSIDE

WHILE it is never good practice to allow a path to become other than what it is intended to be, to neutralise its proper function as a path by allowing shrubs and plants to trespass too far over its course, it is just as easy to err in the opposite direction by insisting upon too much formality and discipline. A happy medium may, however, often be attained between these extremes, and we have found that a judicious selection of plants, set in as natural a manner as possible along our walks, whether these are in the rock garden, the woodland or elsewhere, add a great charm and interest to such places. Incidentally, they save considerable labour by occupying space which would otherwise be a sanctuary for weeds, while they themselves rarely, if ever, require any attention. These paths, I may add, are not paved or otherwise made up. For the most part they are merely faced with a little local gravel and firmed down.

We have, to give a few examples, wide, spreading mats of several of the finer *Acanas*,

the pale emerald *A. Buchanani* and the bronzy *A. microphylla* (*mermis*) being perhaps the most suitable and neither of these offend as some others do by distributing their dry burrs upon one's clothes. These *Acanas* positively seem to like being walked upon, they are rapid growers, beautiful at all seasons and adaptable for sun or shade. Yet they never intrude upon the main footway of the path, for the excellent reason that their leading points are ever being nipped off by the feet of passers-by.

Hardly less may be said of the *Cotulas*, especially the New Zealander which endures the specific title of *squalida*. This makes a dense and delightful carpet of overlapping, fern-like, hairy leaves which will creep over the flat, mound over stones or clothe a vertical and not too dry an edging with the tenacity of Liverwort. It is a fast and vigorous grower, content almost anywhere, but as it is liable to become a nuisance among choicé plants, the woodland or shrubbery walk is the place for it.

Yet another little creeping plant that may be a devastating pest in one spot and a thing of delicate and irresistible charm in another is *Helxine Solierolii*. Though a Corsican, this species will endure any but extremely inclement winters, and even if it should be apparently extinguished by frost its vitality is so great that the merest scrap that survives will spread into a mat of verdure the following summer. *H. Solierolii* has the same clinging habit as *Arenaria balearica*, but its glossy, lettuce-green leaves are larger and, as for its blossoms, these are so minute that they simply cover the plant with a sprinkling of gold dust. An admirable path plant for associating with the smaller native Ferns, Welsh Poppy and other things which will thrive along the shady margins of a woodland walk!

The above-mentioned *Arenaria* is well enough known as ideal for all manner of places which require a minute and close-growing creeper. Few plants are more charming than this when the rocks which border some cool and shady path and even the pathside itself are veiled with its delicate tracery of green, bristling with perky little milk-white flowers.

A plant that will prosper under similar conditions and equally attractive is *Mentha Requienii*, a most dainty mite which appears, as it spontaneously, in all manner of places about our cooler and damper paths. It grows perfectly flat, spreading like a film of moss upon level ground, sowing itself liberally every year and rewarding each passer-by with a whiff of its minty and pungent fragrance. Though not hardy, we can always rely upon some fresh seedlings of *M. Requienii* appearing to make good winter losses, and these grow so fast that they will usually be covered with the tiny mauve flowers—probably the most minute in cultivation—before the season is over.

Mazus Pumilio is also a prostrate little plantling which enjoys a cool spot. It creeps about by means of underground runners and presents us with short, stubby heads of musk-like flowers, usually of a bluish lilac hue. The foliage is a

A USEFUL VARIEGATED HOLLY, *ILEX AQUIFOLIUM ARGENTEA MARGINATA*.

pleasing shade of green, and a healthy specimen of *M. Pumilio* will grow into a close-set carpet. We have found *M. Pumilio* to be rather impatient of our winters, as is its near relation the lovely, pure white, violet-eyed *Mazus* (*Mimulus*) *radicans*. The latter, however, being a marsh plant is not generally suitable for path culture, though some remarkable results have been obtained in ordinary moist or peaty loam.

Another brace of interesting little carpeting plants which are not difficult in a fairly moderate climate are *Pratia angulata* and *P. begoniifolia*. The former (syn. *Lobelia littoralis*) makes a spreading cushion of fleshy, oval leaves which it decks with white, starry flowers followed by blue-purple berries in autumn. The latter is larger in every way, with round, hairy leaves and plum-coloured fruits. Both plants seem to appreciate a shady and sheltered nook, and there are one or two other kinds listed by the best nurserymen which fully deserve a trial.

Among the happiest of the plants which adorn our woodland paths are *Saxifraga cuneifolia* in one or two forms and *S. Geum* with its round, dentate leaves held stiffly on long, narrow stems. The former is a vigorous, hearty little plant which will quickly cover a wide space with a jostling crowd of dark green rosettes and hold its own with most things. It enjoys a cool, sun-screened place, as does the other, and both produce elegant sprays of white flowers like miniature London Prides. Other members of this clan also crop up at times about the sides of the paths where a mossy stump or rock affords a suitable resting place for seed. One of the prettiest of these I strongly suspect to be the offspring of *SS. Geum* and *umbrosa*, but one hesitates to speculate further into the mysteries of these charming colonists.

Some of the creeping *Toadflaxes* are admirable for the margins of such walks as are enjoyed by lovers of cool and moist conditions, and these will often thrive as well on the flat as among rocks. One of the most beautiful is *Linaria hepaticæfolia*, with large, fleshy leaves and violet flowers. But even more choice are *L. pallida* with big clear lavender, fragrant blossoms and its exquisite white form. Very dainty also is the shy little *L. aquitriloba*, which will cling to a vertical rock face and prove a suitable companion for some of those more lowly creepers mentioned earlier. Though often a very murrain in the rock garden, these *Toadflaxes* can be put to such a use as is here suggested, when their undeniable beauty may be appreciated at its full worth.

Many of the dwarfier *Ericas* are good for skirting a walk where conditions are suitable, and for a partly shaded corner where there is some natural moisture nothing can be more delightful than a patch of *Gaultheria trichophylla*. Along with such shrublets as these we have also used *Spiraea decumbens*, *Bruckenthalia spiculifolia*, *Bryanthus empetrifolius* and the always welcome *Polygala Chamæbuxus* in several varieties.

Walsteinia trifolia, with yellow flowers like a *Potentilla*, and *Tiarella cordifolia* will make a cheerful and harmonious blend of colour and form, and for a sunny place in poor, hot soil a few plants of *Dianthus deltoides* and *DD. graniticus* and *cæsius* will soon establish hearty colonies which will give a bright display throughout the greater part of summer and autumn. Nor could one find a better site for the prostrate *Thymes* than along the margin of some sunny path, with a tuft of *Hypericum coris* or little colony of *Tunica Saxifraga* fl. pl., or *Veronicas* *Trebane*, *Bidwillii* or *rupestris* to lend "character" to the effect.

Indeed, one might extend this list indefinitely, for not only is the selection of suitable plants a vast one, but paths vary enormously in their

nature, in width and situation, and each one, or section of one, will demand its own treatment and particular class of planting. To give one final example, I know a shady woodland garden walk whose margins, right to the footway, are carpeted with moss. In the moss are several varieties of dwarf Ferns, singly and in groups, and along with these are little colonies of hardy

Cyclanemus and here and there a patch of Wood Sorrel, both the type species and the exquisite rose form. There is little or nothing more, beyond perhaps a few *Snowdrops* for the early year, yet one could hardly desire a more restful and beautiful lot of path planting, the very simplicity of which is one of its most entrancing features.

Nash Wells.

A. T. J.

PLANTS FOR FAVOURED GARDENS

(A previous article on this subject appeared in the issue for December 2, last, page 6-12.)

IF the common large-leaved *Mesembryanthemum*, such as the one which hangs in huge mats down the Lizard cliffs, were the only sorts hardy enough for English gardens, one might without much loss ignore the whole tribe, except for wild gardens in favoured places, for these are, most of them, too coarse and rampant for ordinary garden use. But some of the smaller sorts are of such good habit and such vivid beauty as to deserve a conspicuous place in any garden mild enough for their survival. The dazzling orange *M. aurantiacum* is hardy enough to stand at least mild winters in favoured Cornish gardens, and the same applies to some of the grey-leaved sorts with small flowers of a cool pink. Imagine a rock face or a wall of grey weathered granite and against it low cushions a yard or two across entirely made of flowers shaped like those of *Aster Anellus*, some white, some flushed, some deep violet rose, and one of a magenta so splendidly intense and pure that it would soon fatigue the eye. One of the best of all is means, a small flower of a rare orange scarlet overlaid with a sheen of violet.

I wish someone who has tried these in an English garden over a period of years would tell readers of *THE GARDEN* of their experience. Am I right in thinking that there are many gardens in the south-west near the sea where a number of the species, including those I have referred to, survive or would survive out of doors? At any rate, if hard weather does come, "Mesems" are the easiest of plants to save—any morsel stuck into a sandy box will grow. Bits shoved into almost earthless clinks of a wall will make strong tufts in a season or two.

A note of Mr. Woodall's in these columns some years ago put me on the track of *Olearia Traversii*, and I can gratefully bear out what he said of this very useful evergreen tree for gardens near the sea. It grows fast, stands any amount of wind, and while it cannot compete with the showy treasures

of Cornish gardens, it is certainly most attractive in a suitable place. I know it best in a garden where it stands on either side of a broad slide of

THE BRILLIANT CRIMSON FLOWER HEAD OF *TELOPEA SPECIOSISSIMA*.

granite backed by grey rocks, with its silvered leaves bright against the sea. I gather that this is a plant hardy enough even for the north-east of Scotland, provided that it is near the sea.

Olearia macrodonta is another *Olearia* that stands a lot of wind. It makes an excellent fast-growing hedge, stands cutting fairly well and, unlike *O. Traversii*, is beautiful in flower, yet this is not a plant I can care much about. It often looks rather stale and dusty, as if it needed freshening up after an August spent near a motorway road. *O. semidentata*, on the other hand, keeps its freshness always, till it gets very old and scraggy. Few shrubs are more beautiful in leaf. Not even *Senecio compacta* or *Tenacium latifolium* has a finer grey. When I see these

grey-leaved plants scattered about a garden I always want to group them together so that they may help each other. It is then that contrasts of form (such as *Yucca recurvifolia* spiking up behind a bank of *Senecio*) can make their fullest effect. Moreover, a sufficiently broad grey background makes the perfect foil for many more conspicuous plants, especially for bulbous plants of distinctive form or colour. I have never seen the greenish white bells of *Hyacinthus candicans* look better than in the company of *Olearia Traversii* and the shrubs I have mentioned, just as *Teucrium fruticosum* (on a wall) makes an ideal backing for *Cladiolus primulinus*, especially the pale yellow forms.

It is odd that nurserymen do not more commonly offer *Pittosporum crassifolium*, for it is easily raised from seed, and good seed (unlike that of the nearly related *P. Fairchildii*) is freely borne. It ought to be easy to supply pot plants at not more than, say, 24s. or 30s. a dozen. The plant is certainly one of the best of all for a tall hedge in wind-swept gardens near the sea; better even than *Escallonia macrantha*, in that it robs the ground much less. It is perfectly evergreen, will stand a lot of overshadowing, and survives even the first shock of Atlantic gales unharmed. It is very beautiful in form and colour of leaf, the maroon-crimson flowers, though not showy, are pleasant to see, and the green seed-pods make a most decorative addition to the pattern. If it were better known I feel sure that *P. crassifolium* would be largely used for hedges in sea-side gardens here, as it is in New Zealand.

P. eugenoides, which spreads a delicious scent of honey through the garden in winter, stands the wind much less well. *P. tenuifolium* is also well worth growing, if only for its scent, and the well known Silver Queen is very decorative in its odd way.

I have referred before in these columns to *Prostanthera violacea*, which makes a tall cloud of violet purple in favoured gardens in spring. This is a plant which will surely be commonly grown for indoor decoration when it is better known. In a white or grey room a plant of it in a pot is at least as effective as a very good *Schizanthus*, and it is perennial and needs little, if any, staking.

Psoralea pinnata is another splendid plant for a favoured garden. It grows very rapidly into a tall bush of narrow leaves with a profusion of bright rosemary-blue, pea-shaped flowers in May. Even this, though too large a grower for small rooms, would, I imagine, make a fine plant for indoor decoration in an entrance hall or a conservatory.

Many would pass by a bush of *Pentstemon rugosum* when in flower, for its hanging horn-coloured lanterns pencilled with red, lovely as they are in detail, are not very conspicuous; but few would pass by *P. serpens* even when out of flower, for its serpentine trails are arresting and queer even when they are not hung with lanterns of scarlet. The flowers of this are bright vermillion with a pencilling of deeper colour. The plant will grow as a bush, but perhaps looks better against a wall.

Pentstemon is a lovely sight in May when a tall dark green bush of it becomes smothered with white plumes. It is worthy of a choice place even in a garden wild enough to grow *Clethra arborea* to perfection.

I was glad to see that in the notes of Mr. Combs, which to me always seem one of the most valuable features of *The Garden*, *Rhododendron Lady Alice Fitzwilliam* has been recommended as a plant for the cool greenhouse. In favoured gardens, in Somerset as in Cornwall, this does splendidly out of doors, but elsewhere it could hardly be grown in any garden where the birds

could be sheltered from more than a few degrees of frost. Perhaps some reader who has a greenhouse full of the conventional *Primulas*, *Geraniums* and *Cinerarias* with may be a plant or two of *Azalea* and *Cytisus fragrans* as the only shrubs, will feel tempted to try a plant of this incomparable *Rhododendron*, for it adds to the beauty of its white trumpet flowers and pink flushed buds the advantage of a scent as good as that of *Honeysuckle*. It is quite easy to grow even in a chalk country if the pot is watered with rain water, and it will not grow too large for a greenhouse staging.

Another sort which is more beautiful than an array of *Caleolarias* is *R. cilicalyx*; this is unscented. Its huge flowers are white or pale pink, slightly ruffled and of a wonderful texture. This does all right out of doors in favoured gardens, but even there it is better grown under glass, as the flowers are too large and fragile to stand buffeting by winds.

Will someone who has had experience of growing greenhouse *Rhododendrons* out of doors contribute

some notes on *R. Sestertianum*, *R. Comtesse of Haddington* and some others (e.g., *Gibsonia*) certainly do well. I want to learn about sorts such as *Fosterianum*, *Ventrianum* and *Princess Alice*. Is there any chance of success with the Japanese hybrids?

I will end these notes with a suggestion which I venture to offer to some enterprising nurseryman. How welcome it would be if someone would bring over and put into commerce some more of the fine Australasian plants which have been proved, in the Scillies and elsewhere, to be hardy enough for favoured gardens. At the present moment I do not know any catalogue in which so notable a plant as *Telopea speciosissima*, the Waratah, is yet listed. And can anyone tell me where to get *Dianella tasmanica*?

Would it not be possible to introduce *Hymenoporus flavum*, which is related to the *Pittosporums* and makes a tree profusely sprinkled with loose heads of beautiful scented yellow flowers not unlike those of a large *Jasmine*? Z.

THE VEGETABLE SEED ORDER

ONE could almost write that seed catalogues are at the present time arriving by every post, as our friends the seedsmen realise that this is the period when gardeners, both amateur and professional, are turning their thoughts gardenwards and cudgelling their brains just what to grow the coming season. These catalogues are a very interesting study and of great help to many in assisting them to make a selection, but one need not emphasise the fact that every seedsmen worthy of the name puts forward the best descriptive matter to advertise his wares. There are, therefore, one or two preliminaries that should receive consideration before we turn to these interesting lists. The first point I would make is that all varieties do not succeed equally well in all districts. Because, for example, a particular kind of Potato does well in one neighbourhood, it does not follow that it will do equally well in the next. It may, perchance, do even better or, on the other hand, may prove an absolute failure, and this effect may be seen in varying degrees through nearly every different kind of vegetable. I would, therefore, urge would-be growers, and especially those who are new to the

locality, to enquire of friends, neighbours and other growers in their particular district as to what varieties do well before making out the seed order. Following this train of thought, I would recommend those who are desirous of trying a few novelties, the behaviour of which will probably be unknown in their districts, only to grow experimentally this first season and to watch the results. They will then know whether to grow again next season in larger quantities or to discard owing to poor results.

The next bit of advice I would tender, as an old stager at vegetable growing, is, get the very best seeds procurable, for only from first-class seeds can first-class results be expected. The best seeds, obtained from a really reliable source, are not too good for anyone. It is no use buying cheap seed and only gaining a 10 per cent. result, when, by purchasing the finest procurable, you can get a 90 per cent. return. It must, however, always be borne in mind that any seed will be likely to fail if the soil is not prepared in a proper way and careful and watchful attention accorded afterwards. Proper preparation consists in deep trenching, never mind what class the soil may be, so as to bring the subsoil to the surface and

A RELIABLE CARROT—NEW INTERMEDIATE.

burying the surface soil. Combined with this effort should be the adding of suitable manures, for plants cannot be expected to thrive unless they can get their roots well down and find the necessary foods they want to nourish them. For light, hot soils select the cooling and binding cow or pig manures, and for those of the heavy, cold, water-retentive class use the lightening manure from the stables with the bedding straw left in. Proper after-care is essential. Thinning must be done when required. Such vegetables as need support must be staked, and before the time arrives to carry the staking out the growing plants must be worked around with a Dutch hoe. This will keep weeds at a minimum, the soil stirred and aerated. The stirring reduces the call for watering, but when water is required give proper soaking at intervals, not a light daily sprinkle, for one must realise that it is not on the surface, where it soon gets dried out, that plants require water, but deep at the roots. These are the main directions in which care is necessary, though there are others. Earthing up, watching for pests, feeding growing plants with a dusting of a reliable fertiliser from time to time, and such other matters are all necessary for satisfactory results.

On this occasion I propose to write primarily for those who grow for consumption purposes, adding any little data that may interest those who wish, in addition, to raise vegetables for exhibition. The owner of a small garden, such as is attached to the average house or cottage, will be borne steadily in mind. The primary selections are for such, but further groups are added suitable for larger areas. In naming varieties it must be understood that these are only referred to as having proved excellent in our own particular neighbourhood, and it rests with the reader to ascertain their success in his own locality.

For the small garden the following list of kinds and varieties will carry him practically the whole year round, and if it seems a large one, close observation will point to the fact that even in a small garden most of them are attempted and grown.

Beans, Broad.—Broad Windsor, Improved Green Longpod and Leviathan.

Beans, Runner.—Prizetaker and Scarlet Emperor.

Beet.—Dell's Blood Red, Cheltenham Green Top, Selected Globe and Selected Purple. For exhibition bore as recommended later for Carrots.

Borecole or Kale.—Cottager's Kale, Labrador Kale and Victoria Kale.

Broccoli.—Late Queen, Leamington, Model and Snow's Winter White.

Brussels Sprouts.—Aigburth, Dwarf Gem and May's Northall.

Cabbage.—Early.—April, Ellam's Early and Flower of Spring. Summer and autumn.—Rosette Colewort. Autumn and winter.—Winningstadt.

Carrots.—Long Surrey Model and New Intermediate. A difficult vegetable for exhibition. On heavy ground bore holes with a crowbar and fill with a suitable light soil mixture.

Cauliflowers.—Autumn Giant, Early Forcing, Early Giant, Magnum Bonum, Snowdon and Walcheren.

Lettuce.—All-the-year-round, Bath or Brown Cos, Hick's Hardy White, and Superb Cos. For show work two good coloured varieties are Golden Queen and Marvel.

Onions.—For spring sowing.—Ailsa Craig Selected, James Long Keeping and Wilkes' Exhibition. For autumn sowing.—Autumn Triumph, Mammoth White Tripoli and Red Italian Tripoli.

Parsley.—Exhibition Curled.

Parsnips.—Student, and Tender and True. For exhibition work bore ground as noted for Carrots; larger holes, further apart.

Peas.—Edwin Beckett, Autocrat, Gradus, Duke of Albany and Quite Content—the last named

being a fine variety but a little difficult on light soil.

Potatoes.—Earlies.—Dunmatar Castle, May Queen, Midlothian Early and Resistant Snowdrop.

POTATOES KING EDWARD (IN BASKET) AND GREAT SCOT.

Second earlies.—Arrau Comrade and British Queen. Maincrop.—Arrau Chief, Kerr's Pink and King Edward. It is rather a doubtful point whether in a small garden Potatoes, other than earlies, are really profitable for the area they occupy, except, of course, for exhibition work. Exhibition coloured varieties.—Edgecote Purple, Edzell Blue, Exhibition Red, Mauve Queen, Mr. Breeze and Red Kings.

Radish.—Beck's Scarlet and French Breakfast.

Rhubarb.—Victoria and The Sutton.

Savoy.—Drumhead, Early Elm and Green Curled.

Shallot.—Exhibition Red and Large Brown.

Turnip.—Early Milan, Golden Ball, Green Top and Snowball.

For those who have a little more room or wish to substitute there are the following:

Beans, French.—Canadian Wonder and Ne Plus Ultra.

Celery.—Aldenharn Pink, Aldenharn White, Invincible White and Standard Bearer.

Celeriac.—Smooth Prague.

Leeks.—Musselburgh and International.

Tomato.—Bide's Recruit and Sunrise for reds, and Golden Perfection and Golden Sunrise as yellows.

For the larger kitchen garden the following may be added:

Artichoke, Jerusalem.—Any good white rather than a purple.

Asparagus.—Connover's Colossal and Reading Giant.

Chicory.—Witloof.

Endive.—Batavian and Green Curled.

Seakale.—Lilywhite.

Spinach.—Prickly, Victoria, and, for light textured soil, New Zealand.

Finally, where ample space abounds, the list may be completed with the following:

Artichoke, Globe.—Green Globe.

Beans.—Climbing French.

Capsicums.—Where glass is available, Long Red and Long Yellow, these being interesting in a large show collection.

Cardoons.

Chives and Garlic.

Cucumber.—Where heat obtainable, Ideal and Lockie's Perfection. In frames on mild hot-bed, Stockwood Ridge Cucumber.

Kohl Rabi.—Early Purple Short Top and Early Short Top Green.

Maize.—Country Gentleman.

Salsify.—Sandwich Island Mammoth.

Scorzonera.

Suede.—Any good culinary variety.

Vegetable Marrow.—Long Green, Moore's Cream, Pen-y-byd and The Sutton.

The lists shown will I think carry most gardeners forward, and those aiming at shewing large collections will be able to add the few "fancy" sorts omitted. Sowing for succession should be aimed

at, and it should be remembered that a number of sowings at intervals, sufficiently large to meet one's needs, is far better practice than one large sowing, especially with such kinds as Lettuces, Radishes, Turnips, Peas, Spinach, etc.

EDWIN BECKETT.

A Beautiful Flowering Plum

PRUNUS CERASIFERA ATROPURPUREA MOSERI PLENA is the name of one of the most beautiful of the flowering Plums we possess, and one that may be classed among the earliest flowering, as the tree is covered with almost fully-expanded blossoms well within the first week of March. It is a glorious variety of *Prunus Pissardi*, and flowers just a little later than the well known purple form of the Myrobalan or Cherry Plum. It is, however, superior in every respect, being much larger, semi-double, with stronger foot-stalks and much more substance in the blooms, which are more cup-shaped than the single blooms of *Prunus Pissardi*. The flowers are of a soft yet rich pink shade in colour, more approaching the colour of *Prunus triloba*, and the foliage resembles the purple *Prunus*. The tree we have has not yet attained sufficient dimensions for cutting; but judging by a spray that was cut and placed in water, it will be of real value for decorative purposes, the blooms being less liable to drop than those of some of the others now in flower, to wit, the common Almond; and though I have not seen it used for forcing, it should, I think, prove of inestimable value for this purpose, and thus add variety to the already long list of shrubs amenable for this treatment.

E. B.

THE OLD - FASHIONED RANUNCULUS

AN old-world flower, with a strange air of precision about it that still, however, retains a large measure of popularity, judging by the readiness with which the flowers sell in early spring from the florists' windows and street vendors' baskets. It is durable and decorative when cut, there can be no query on that score and, to those who know it as it grows, very attractive in the garden. The strange thing is that, while it sells readily when grown, few people do know it as it grows, for it is rarely that one comes across it in gardens.

Yet every bulb list offers the quaint claw-like tubers and a small group of a few dozens here and there well repays the care and attention necessary to bring them to perfection. They have been divided - more or less loosely, it is true - into three classes: French, Persian and Turban, varying both in height of plant and size of bloom. The French are the largest flowered and the tallest; the Persian, dwarfer and earlier; while the Turban are intermediate between the two classes. All come from *R. asiaticus* and have been obtained by generations of gardeners selecting, inter-crossing, hybridising, etc. As a rule the plants are not hardy enough for autumn planting, so that February proves the best season at which to do this. The soil can scarcely be made too rich, though everything in the nature of manure, etc., which is dug in must be very sweet; nothing rank should ever be permitted to come near the roots. Dig the ground deeply, add the manure in the form of old decayed stable manure (that from a spent hot-bed is excellent), leaf-mould, etc., and allow time for this to settle before planting. This is a point upon which too great stress cannot be laid when dealing with any bulbous or tuberous plant. Give the soil time to settle, then plant.

If one plants soon after digging is finished, the consolidation of the ground takes place with the tubers in it and they may be carried down thereby to a greater depth than they should be. These Ranunculi are sun-lovers, so that an open position should be given them. Plant each tuber with the points of the claws downwards, at a depth of about zins., and eins. to eins. apart. Each tuber should have a little coarse sand shaken round it at the time of planting and growth is hastened by soaking the tubers in water for twenty-four hours before planting. Make the soil fairly firm to finish and then leave alone until the plants are well through the ground, when the space between them should be thoroughly hoed. It is very generally recommended to cover the surface with straw, bracken or some light litter but—planting during the latter half of February—I have not found this to be an advantage. Progress is fairly rapid and the pushing up of the buds should be watched for. This marks an important stage in the plant's development, for from then onwards they must be guarded from drought or they are liable to go blind. Do not water when the surface is caked; this is bad in two ways for, firstly, a great deal of the water will run off, and secondly, it makes the already caked surface harder, so that it draws up the moisture from below (where the roots are), more rapidly still.

During May there should be a really fine show of brilliant flowers: in some cases self coloured, in others white or light, edged and barred with red, as evenly as a Picotee. As a rule the plants seed freely and, where this is so, it is an interesting operation to raise a batch of young seedlings from these, which will attain flowering size in three years. On no account must the plants be lifted

until the last of the foliage has completely died away, which will be about the middle of June; then the tubers should be taken up, dried, and stored in bags of dry sand in a frostproof place until planting time recurs. Some years ago I used to grow a small bed of these each year and, after taking up the Ranunculus tubers, had ready a sufficient number of *Petunias* or *Minuluses* in pots just coming into flower to fill the gap. Out

these went at once and thus the bed very soon became flowerful again. Most people will probably be content with what are known as "mixed" of one or other type, but those who are very keen should try the following distinct named and fine Turban varieties: Grootvorst, crimson; Hercules, white; Merveilleuse, yellow; Romano, scarlet; Seraphique, citron yellow; and viridiflora, green with scarlet edge. H. W. CANNING WRIGHT

NOTES OF THE WEEK

WE are now, from the point of view of gardening outdoors, at the very dullest time of the year. Comparatively few berried shrubs retain their fruits so long and the late-blossoming species have quite finished. Only Snowdrop and Witch-hazel, Winter Sweet, Cyclamen and Violet, with here and there a precocious Primrose, herald the coming of Spring. There is, however, no reason why the garden should not be effective these January days for, unless the weather happens to be frosty, unattractive corners can be remedied straight away. Here a clump of silvery Birches, there a group of red-stemmed Dogwoods or Golden Willows or the vivid green stems of *Leycesteria formosa* will increase the interest.

The Journal of Pomology.—It was with considerable pleasure that the Editor recently received another number of the Journal of Pomology. An editorial note points out that a year has elapsed since the issue of the last number and elsewhere it is explained that the responsibility for publication has been taken over by the Horticultural Research Stations at Long Ashton, Cambridge and East Malling. Mr. E. A. Bunyard remains Editor. He is, too, a member of the Publication Committee, which also includes Prof. Barker of Long Ashton, Prof. Biffen of Cambridge, Messrs. H. E. Dale and H. V. Taylor of the Ministry of Agriculture, and Mr. R. G. Hutton of the East Malling Station. The list of "Associate Editors" contains the names of no fewer than five Fellows of the Royal Society and a great array of talent besides. There seems every reason, then, to expect a long and extremely useful life for the Journal which, by the way, is

to be known henceforward as "*The Journal of Pomology and Horticultural Science*." It is, as heretofore, a quarterly publication and the annual subscription is 15s. The publishers are Messrs. Headley Brothers, 18, Devonshire Street, Bishopsgate, E.C.2.

Dwarf Broad Beans.—Dwarf Peas have become a commonplace. It is possible now to obtain quite dwarf varieties, admirable of flavour and excellent in appearance both in the pod and when "shelled." No dwarf Bean has so far superseded the useful Scarlet Runner, though by pinching it is quite feasible to grow Painted Lady, with its quaint parti-coloured blossom, as a dwarf. Indeed, it is largely so grown in some districts for market. The latest development is with the Broad Bean. Now, especially if sown early, the Broad Bean cannot be considered a tall grower and the advantage of a dwarfer stock may not, at first sight, be apparent to everyone. The fact remains that in small gardens the ordinary strains of Broad Bean shade a great deal of ground. A further point in favour of the dwarfs is that they are exceedingly unlikely to get damaged by strong winds and certainly need no staking. Messrs. Sutton, who have been selecting these dwarf strains, are putting two excellent varieties on the market this season called respectively Sutton's Little Marvel and The Sutton. The former is a little the taller and more erect in habit and perhaps a little the heavier cropper. The Sutton, illustrated below, is also wonderfully prolific and scarcely taller than a carrot! Both are of first-rate flavour and mature quickly and will be indispensable where Broad Beans are grown in frames for early work.

THE NEW "SUTTON" BROAD BEAN.

CORRESPONDENCE

CHRYSANTHEMUM TOKIO.

MR. C. HAKMAN PAYNE is under some misapprehension about this variety, or possibly two varieties have been given the same name. I was growing Tokio in some quantity from the early eighteen-eighties onwards, and its colour was not pale pink but a very vivid orange red. It was a very useful late flower of the strictly decorative class, spoilt instead of improved by disbudding, easily grown and of excellent constitution. It was largely used for Christmas work by the florists in my neighbourhood. I am glad to see it still included in Mr. H. J. Jones' catalogue and described as "bright red, small flowers produced in light sprays, fine for table decoration."—G. H. ENGLEHEART, Dinton, Salisbury.

I had charge of a good-sized conservatory, and I had several basket plants hung from the roof. I enclose photographs of some of them. I endorse the remarks of your correspondent "H.W.C.W.," who seems to have a wide experience of basket

A FINE BASKET OF NEPHROLEPIS EXALTATA.

MAGNOLIA CAMPBELLII.

I WONDER if you care to have the enclosed photographs of a *Magnolia Campbellii*, planted in this garden by the late Mr. Chambers about thirty-five years ago. It grows over 50ft. up, at the east end of a spur of the Haslemere greensand, and looking (as you can see) across the weald to the South Downs. It flowered for the first time early in 1921, but did not repeat the effort last season, nor, I fear, does it mean to in the coming one.—W. J. H. WHITTALL.

[The pictures, which shew a tree some 15ft. or 20ft. high and wreathed in blossom, are, unfortunately, unsuitable for reproduction.—ED.]

SHRUB SPRAYS FOR DECORATION.

I HAVE been much interested in the correspondence in THE GARDEN on evergreen and berried shrubs. Why is it impossible to buy sprays of these for house decoration? Shops are filled with enormous and costly *Chrysanthemums* and *Carnations* which are, for the most part, far beyond the means of the ordinary purchaser. How nice if one could obtain at reasonable cost a box containing branches of *Euonymus*, *Eleagnus*, *Cassia*, *Pernettya*, *Berberis*, *Cotoneaster* and many others too numerous to name. Could not some ladies, who know what table and house decoration means, undertake to supply them? I believe they would readily be bought. From November till end of February, when snow and fogs are plentiful, I hardly ever have a flower in my house, but my rooms are full of bowls and dishes arranged with branches of various shrubs, deciduous as well as evergreen, such as we can grow in the north. How much one would like to add to these some of the more delicate varieties to be found in any good old English shrubbery.—(Mrs.) L. G. BARRON, N.B.

BASKET FERNS.

I WAS very much interested in reading in your issue of THE GARDEN for December 9, 1922, about "Ferns for Basket Culture." Some ten years ago, when residing at Beverley, East Yorks,

plants; but I think the annual remaking of the basket is a mistake. The plant has not had a chance to cover the basket in that time. The basket looks best when the rhizomes have just covered the entire underside of the basket. The photographs enclosed are of baskets 4ft. and 5ft. in diameter, and none of the basket could be seen. I think that baskets, to carry on, want to be no less than 18ins. across the top and 1ft. deep. The compost I used consisted of turfy loam, peat, coarse leaf-soil and a little sand, the peat and loam not less than walnut-size. The baskets when planted were kept in a warm greenhouse for eighteen months. I put in plants out of 6in. pots, and in two years' time the baskets were entirely covered. They were at their best when from four to eight years old. I still have one of the Fern baskets shown in the photograph. The basket has been made up fourteen to sixteen years. In hot weather they were shaded by applying summer cloud to the roof glass and watered three times a week and, during spring and summer, with weak liquid manure. After the second year they were grown in the conservatory, which was barely frost-free in severe weather. I think the secret of this longevity was weak liquid manure.—ROBERT SMITH.

[Two other photographs, not reproduced, shewed equally fine baskets of *Davallia dissecta* and *D. canariensis*—ED.]

WINTER BLOSSOM.

WITH reference to the letters which appeared in THE GARDEN for December 23, 1922, about winter blossoms, it may interest some of your readers to hear that we found the following fifty varieties of plants in flower on Christmas

Day in our garden in Monmouthshire: White Sweet, Purple Veronica, Crimson Veronica, Violet China Rose, Polyanthus Primrose, Blue Primrose, *Chrysanthemum*, *Genista*, St. Brigid Anemone, *Lonicera fragrantissima*, Winter Heliotrope, Antirrhinum, Rambler Rose, Fairy Rose, Climbing Rose Caroline Testout, Triteleia, Pink Helleborus, Christmas Rose, Magnolia (common), Petiwick Yellow Alyssum, White Arabis, *Geum* Mrs. Bradshaw, Strawberry Quatre Saisons, Anubria Alpina Pink, Wallflower, Valerian, *Rosmarinus prostrata*, *Arenaria montana*, *Anchusa myosotidiflora*, Snowdrop, *Potentilla alba*, common Primrose, *Cyclamen europaeum*, *Campanula persicifolia*, Double Daisy, Beedlower, *Pentstemon*, Viola (several colours), Pansy, *Jasminum nudiflorum*, Escallonia, Canterbury Bell, Marigold, *Campanula muralis*, *Cymbalaria* (trailing Toadflax), *Pyrus* (*Cydonia*) japonica and Rose Climbing Papa Gontier.—D. MACNABB (Lieutenant-Colonel).

PERHAPS the enclosed list of 246 species of flowers in bloom in Christmas week out of doors may be of some interest. They are all growing in either Mr. G. W. W. Blathwayt's garden or mine at West Porlock or Porlock Weir. The Citrons, Orange and Lemon had a quantity of buds and blossom knocked off by heavy rain last week, so, although they are carrying large buds just ready to open, they were not actually in flower this week. The same storms finished off a good many other flowers, otherwise the list might have been considerably longer. The Heliotrope, which still bears a few flowers, has stood out in a very sheltered spot for the last two or three winters. The list is as follows: *Abelia grandiflora*, *Abutilon megapotamicum*, *A. large-flowered hybrids*, *Acacia falcata*, *Alströméria aurantiaca*, *Anchusa italica*, *A. myosotidiflora*, *Anemone fulgens*, *A. St. Brigid*, *Aster cordifolius*, *Arenaria montana*, *Araucaria sericifera*, *Aubrietia*, *Arabis albidia*, *A. rosea*, *Antirrhinum inajus*, *Armeria* sp., *Arbutus Unedo*, *Anthemis tinctoria* Kelwayi, *Berberis Darwinii*, *Buddleia auriculata*, *Campanula muralis*, *C. persicifolia*, *C. pyramidalis*, *C. garganica*, *C. linifolia*, *Ceanothus divaricatus*, *C. Gloire de Versailles*, *Convolvulus mauritanicus*, *Cineraria* (large-flowered hybrids), *Cistus crispus*, *C. florentinus*, *Chrysanthemum* (many varieties), *C. frutescens*, *Choisya ternata*, *Cheiranthus linifolius*, *C. mntabilis*, *C. Cheiri*, *C. Harpur Crewe*, *Clanthus puniceus albus*, *Corydalis cheilanthifolia*, *C. thalictrofolia*, *C. Wilsoni*, *Cydonia japonica*, *Cyclamen Coum*, *Coronilla glauca*, *C. emerus*, *Cytisus racemosus*, *C. monspessulanus*, *Chimonanthus traquairi*, *Cuphea ignea*, *Colchicum autumnale* fl. pl., *Cassia corymbosa*, *Calcicolaria integrifolia*, *C. Forgetti*, *Crocus Imperati*, *Celsia cretica*, *Cobaea scandens*, *Citrus* (the Bitter Orange, Citron and Lemon), *Daphne Mezereum*, *D. Laureola*, *D. pontica*, *D. Philippi*, *Dianthus plumarius* (many varieties), *D. caryophyllus*, *D. graniticus*, *Dondia Epipactis*, *Digitalis ambigua*, *D. lutea*, *Diplacus glutinosus*, *Desfontainea spinosa*, *Dendromecon rigidum*, *Datura sanguinea*, *Delphinium Ajacis*, *Echium roseum*, *Eccremocarpos scaber*, *Erodium macradenum*, *E. romanum*, *Erica darleyensis*, *E. carnea*, *E. Veitchii*, *E. melanthera*, *Escallonia macrantha*, *E. langleyensis*, *E. montevidiensis*, *E. sp.*, *Erigeron mucronatus*, *E. speciosus*, *Eranthis hyemalis*, *Euphorbia Characias*, *E. sp.*, *Eupatorium Weinmannianum*, *Eryneum amethystinum*, *E. Olverianum*, *Eleagnus macrophylla*, *Fuchsia gracilis*, *F. Cottinghamii*, *F. microphylla*, *F. venusta*, *F. garden hybrids*, *Gentiana acaulis*, *Gerbera Jamesoni* hybrids, *Geranium striatum*, *G. subcaulescens*, *Geum Borisii*, *G. Heldreichii*, *G. coccineum* Mrs. Bradshaw, *Grevillea rosmariaefolia*, *Gypsophila paniculata*, *G. repens*, *Hamamelis mollis*, *Helleborus niger*.

STRAWBERRIES AND ASPARAGUS.

MR. ENGLEHEART is equally forceful as a speaker and a writer, which is saying much, but it will demand much persuasion, in addition to forcefulness, on his part to convince the gardeners of the country that the selection of runners from maiden Strawberry plants (page 661) spells all the difference between early and excellent results and late and comparatively poor ones. That runners from maidens are preferable none will dispute—it has been freely acknowledged for a couple of generations anyway, probably much longer, but they are by no means always at command. It is not every amateur who is able specially to reserve plants for the provision of runners, and it is in no sense necessary that he shall do so since runners of practically equal excellence and earliness can be secured from one year old plants, as has been proved time after time by skilled cultivators. Mr. Engleheart makes a much stronger point, in my opinion, when he urges early planting; indeed, I venture to express the view that the success which he achieves is more largely due to the early planting, with consequent perfect root establishment before the end of August, than it is to taking runners from maiden plants. Mr. Engleheart is sound, too, in his advocacy of cultivating Strawberries as

annuals. I have proved repeatedly that this system is the best for private gardens, and I know many places in which it is the strict rule. The actual weight per plant may drop a little, but there are more plants from which to gather, while the fruits are finer in size, appearance and quality. With some care Strawberries as annuals can be brought in with the ordinary rotations of the vegetable garden without the least trouble. The conditions of private and commercial cultures differ so widely that the one cannot be compared with the other; commercial growers will never be able to supply hundreds of thousands of plants from maidens in July, and it is as useless to expect it as to suggest it. Squares of turf are better than pots for the runners. Has Mr. Engleheart tried them? The gentle tilt at those who plant Asparagus stools instead of sowing seed need not

be quite attractive, while it is by no means to be despised as a cut flower. The Annual Cornflower (*C. Cyanus*), again, seems to have lost ground of late, which also is surprising. —G. HARVEY.

It does not seem likely that many readers will share our correspondent's enthusiasm for *Centaurea montana*, though some of the better forms, e.g., Lady Florence Hastings, are desirable plants enough. There is something flat and uninteresting about the growth of the plant which is against it. The Annual Cornflower has lost ground because, just as beautiful as of old, it has to compete with improved strains of other annuals, which rather overshadow it. It is, however, admirable for cut flower, and the improved strains of other annuals should not tempt florists to try to improve it, for, in its own way, it is just right. Certainly the white and pink varieties are inferior to the typical blue —ED.]

WINTER SPRAYING.

YOUR contributor's article on "Spray Fluids and Spraying" in the issue of THE GARDEN for December 30, 1922, contains some statements which are perhaps open to question, at any rate from my experience. In the first place, while quite agreeing that spraying is not a matter of "cut and dried rules," I think it is very useful to have a programme or calendar to work to, with reliable formulae, as one is then reminded of the time to apply the various washes, although judgment is, of course, necessary as to whether any particular trees require it or not. In this connexion I have found the late Mr. Spencer Pickering's book, "Fruit Trees and Their Enemies," very useful; the subject, having been a life-study with this gentleman, is there treated in a thoroughly scientific manner. As regards early spraying, I think it is often an advantage to postpone the application of caustic washes until well into February or even March (for Plums). By that time the insects are beginning to move out from

THE "PERENNIAL CORNFLOWER," *CENTAUREA MONTANA*.

the crevices and become more accessible to the action of the chemicals. Where American Blight has been noticed it is an advantage to use an emulsion containing paraffin as well as caustic soda applied with a powerful jet. If caustic soda of sufficient strength be used, viz., 2lb. to 2½lb. to 10 gallons, it is usually considered that the eggs of several insects, such as mussel scale, for instance, are prevented from hatching. Leather gloves are very little protection against caustic soda, and are almost immediately ruined if much wetted. Rubber gauntlet gloves should be worn, and a broad-brimmed hat and goggles are also advisable. I hope you will do all you can to spread the knowledge of spraying and its advantages. It is a subject on which amateurs and smallholders generally are very ignorant. —W. S. GILLES, F.J.C.

THE "PERENNIAL CORNFLOWER."

I SHOULD be interested to hear what is the real objection to what many gardeners call the "Perennial Cornflower," *Centaurea montana*. There are many colour forms and, personally, I consider it quite one of the best, as it is among the easiest, of hardy perennials, yet, emphatically, it is quite out of favour. The greyish foliage, too,

the crevices and become more accessible to the action of the chemicals. Where American Blight has been noticed it is an advantage to use an emulsion containing paraffin as well as caustic soda applied with a powerful jet. If caustic soda of sufficient strength be used, viz., 2lb. to 2½lb. to 10 gallons, it is usually considered that the eggs of several insects, such as mussel scale, for instance, are prevented from hatching. Leather gloves are very little protection against caustic soda, and are almost immediately ruined if much wetted. Rubber gauntlet gloves should be worn, and a broad-brimmed hat and goggles are also advisable. I hope you will do all you can to spread the knowledge of spraying and its advantages. It is a subject on which amateurs and smallholders generally are very ignorant. —W. S. GILLES, F.J.C.

PLANTS WHICH TURN GOLD IN WINTER.

I KNOW of two "golden-leaved" plants which have the curious habit of becoming bright gold in winter and then in spring returning to a normal green again. Possibly there are others which do this, but the only two of my acquaintance are the golden form of the Scots Fir, *Pinus sylvestris aurea*, and the golden Thyme, *Thymus Serpyllum aureus*. The golden Scots Pine is, I think, a rare tree. I have only seen four specimens altogether. One, which I obtained with much difficulty and planted in a rock garden near Sheffield, two small ones which we treasure here at Stevenage, and the fourth is at Underley, a wonderful specimen which—writing from memory—I should say must be 15ft. or 20ft. high. For *Pinus Sylvestris aurea* seems to be a very slow grower. Mine, which I have had for four or five years, have not added more than 5ins. or 6ins. to their stature in that time. In mid-autumn they begin to turn yellow, and by Christmas are as gold as a guinea, bright and cheerful and quaint. The golden Thyme came to me from Mr. E. Charles Buxton, who, I believe, collected it wild on the Welsh hills. A delightful gift to receive, for I am fond of all the Thymes; they are so well bred and well

behaved, and I like the scents they "use," and this golden form has the happy gift of looking cheeriest during the dirtiest months. All summer it looks like the ordinary wild Thyme of the downs, and buses itself in spreading into comfortable fragrant mats and cushions. Then one winter's day you come along and think that someone has dropped their gold chain-bag in the rock garden. Better than that though—for folk who drop gold chain-bags about always come back and claim them—is *Thymus Serpyllum aureus* in its winter "plumage"!—CLARENCE ELLIOTT, *Stevenage*.

A FINE FOXGLOVE.

I HAVE been interested in reading the articles on "Perennial Plants from Seed." With reference to Foxgloves, I should like to mention that Messrs. Sutton and Sons have a very beautiful form not mentioned in the article, called Sutton's Giant Primrose. It is really a deep cream and bears long spikes of large flowers. A very pretty combination which we happened to have this year in our garden was this Giant Primrose Foxglove, *Delphinium Sutton's Seedling Belladonna*, and Canterbury Bell Sutton's Cup and Saucer Pink—CONSTANT READER.

THE USE OF CLOCHES, PARTICULARLY FOR HALF HARDY ANNUALS

MANY amateurs with small gardens and no provision for a moderate degree of heat are compelled to purchase half hardy annuals and similar plants, if they require blooms at the usual time. The writer has experimented for some years past with cloches, of which there are several patterns on the market, and his results are sufficiently encouraging to be worthy of record.

The illustration shews one of the types which he has used, one cloche being shewn lifted out of the way for watering purpose, and doubtless other types would give equally good results provided some ventilation is possible. The method of use is quite simple; a seed bed is prepared, preferably incorporating a good supply of some preparation for killing soil pests over a larger area than will be covered by the cloches, about a fortnight before sowing.

The seeds are then sown and the bed covered with slates until germination has started, the cloches being placed over the slates and the ends closed with glass. The temperature inside from the action of the sun is considerable and germination is usually very good.

As soon as the seedlings appear the cloches are covered with some opaque shading, such as "summer cloud," to prevent the sun scorching the young plants, which in normal circumstances, make very good progress. These seedlings are thinned out early or transplanted under other cloches, where they are kept until they are large enough for their permanent quarters. In this way half hardy annuals, such as Asters, Zinnias, Phlox Drummondii, etc., are raised and are practically as forward as plants raised in heat and generally more sturdy.

A few results may be interesting. Asters sown about the last week in February, if the weather is open, or as soon as possible after that date, are fit for planting out about mid-May for flowering early in August. *Eccremocarpus scaber* raised in this way flowered in July, *Antirrhinum* early in

August, while Dahlias—the seeds of which were germinated in the hot cupboard of the bath-room early in March and planted out under the cloches at once—flowered in August. Some have actually bloomed late in July.

Many other uses to which such appliances can be put will doubtless be found; for example, hardy annuals can be made to bloom much earlier, the germination is more certain and the results well repay the trouble. Clarkias, for example, sown late in February will bloom early in June and in the hot summer of 1921 these plants seeded themselves and the resulting seedlings were shewing buds in the middle of October. These were protected with the cloches and bloomed fairly well till severe frost cut them down in November.

Clumps of Sweet Peas, each under a separate cloche, sown in October usually progress very well.

A certain proportion are lost in very severe weather, though a litter of dried leaves under the cloche gives some protection; and it is advisable if the frost is heavy to cover the cloches with matting. Other Sweet Peas raised in a cold frame are regularly put out in February and in exceptional weather have been planted out in January, the cloches only being removed when the plants become too tall; these have bloomed in the third week in May and in a very good year were still healthy at the end of September.

The cloches are exceptionally useful in raising very small seeds and the writer gets very much better results than he can obtain with a cold frame, the supply of moisture being much better maintained. For example, the growth and germination of such minute seeds as *Buddleia Veitchii* has not been good in a cold frame, but in the open, protected in the manner indicated, the results were excellent.

Small plants which are prone to rotting or to the attacks of slugs are protected with safety, and seedlings of *Primulas*, such as *Cashmeriana*, *Bulleyana*, *Cockburniana*, are given a plentiful dusting of soot, which is never washed away as watering will be unnecessary. In special cases a collar of zinc sheet round each plant will form an absolute protection from slugs. The writer has by this means succeeded in wintering *Primula malacoides* in the open ground.

The advantages of sowing seeds of perennials as soon as they are ripe are well known and young plants of *Lupinus*, *Gallardias*, *Delphiniums*, etc., which otherwise fall a ready prey to slugs will make good progress and flower well the following year. In mild weather the writer has actually had self-sown *Dahlia* seedlings appearing in January and surviving the winter.

Greenfly has to be watched; it is quite common to be troubled with this pest in November and sometimes again as early as February.

When the weather is mild and dry, the end of the cloche or line of cloches least exposed to the wind is left open to allow as much ventilation as possible. Last winter the writer tried the experiment of putting a tent-shaped cloche, with ends closed with glass, under a larger barn-shaped cloche, also with ends closed, the idea being that air which is not in movement is about the best non-conducting medium that could readily be found. Some half hardy plants and one or two very robust hardy plants were planted under the inner cloche. The results were not unexpected; the frost was kept out, but all the plants eventually died from want of ventilation.

Blackheath.

D. H. HALL.

SHEDS HOW THE CLOCHES ARE MADE AND USED.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Broad Beans.—A small sowing of a Longpod variety may be made whenever the climatic conditions are favourable. This sowing should be made in double lines 6 ins. apart, with 2 ft. or 3 ft. between the double rows. The seeds should be placed 6 ins. apart and 2 ins. deep. Those sown in November should be well through the soil, and the hoe should be employed occasionally between the rows when the ground is dry enough.

Boxing Potatoes. It is time early varieties were sorted and those suitable for seed set up in trays or boxes. Medium-sized tubers are best, but we find we have very few of these, and it will be necessary to cut the larger tubers. The boxes should be placed in a light, airy shed from which frost can be excluded. By keeping the tubers as cool as possible short-jointed, sturdy growths should result.

Shallots.—These are often acceptable, especially when the Onion crop is below the average, and now is a suitable time for planting the bulbs 1 ft. apart.

Seakale. If not already done, this crop should be lifted and the ground trenched, taking care to pick out any roots as the operation proceeds. When the main stem has been relieved of its side roots the Seakale will be ready for forcing, but darkness is essential for this crop. A mushroom-house is an ideal place for Seakale; but it is not a necessity, as a warm greenhouse is also suitable if light is excluded. The best of the side roots must be retained for next year's crop. They should be cut into 6 in. lengths, tied up in bundles, and buried in ashes until planting-time arrives.

The Flower Garden.

General Work.—The flower garden should always be made as attractive as possible at all times of the year, but in many places the shrubberies and the ground beyond the flower garden proper do not receive the attention they should. Here is scope for producing bold displays of flowering trees and shrubs, while corners judiciously placed would be welcomed, especially during the winter months. Clumps of Lilac, Laburnum, Spiræa, Forsythia, Philadelphus, Deutzia, Pyrus floribunda and a host of other plants are suitable. Among the peat-loving plants will be found the Rhododendrons, Azaleas (of which there are some beautiful varieties) and the various kinds of Heath, particularly the graceful Erica codonodes and E. Veitchii. We also make use of Bamboos, the Pampas Grass, the sweet Lavender and Rosemary, while further afield are planted patches of the common and double Gorse, while the golden Spartium junceum is in full beauty about August, when flowering shrubs are little in evidence. This plant is easily raised from seed, but it will be two or three years before it makes a good display. At this season the lawns should be kept free of leaves, etc., and when the ground is not too wet the roller should be employed, while any bare places may be returfed and holes or depressions made up. Every part of the flower garden should be kept as neat and tidy as possible.

Under Glass.

Cucumbers are never too early, and where the necessary facilities are available a few seeds may now be sown. A low small house is needed, and the temperature should not fall below 60°. At this season a little bottom-heat is helpful towards germination, and if it is not possible to make a small hot-bed in the house a large box filled with fermenting material will answer the purpose. The seeds should be placed singly in small pots, and until the seedlings are through the soil no water will be needed if the compost was just moist at the time of sowing. Never allow the plants to become starved, and when the roots are through the soil repot into 5 in. pots, and then in a week or two transfer them to the beds of loam on the stage. Telegraph is still fancied by many, but we have discarded it in favour of Everyday and Delicacy.

Melons.—So far as raising the plants are concerned, they need the same treatment as Cucumbers, but to grow them successfully a separate house or division is required.

The Hardy Fruit Garden.

Spraying Fruit Trees. This important work should be carried out on a calm, mild day after the pruning has been completed. An alkali wash ought to be employed, and care should be

taken to wet the whole of the trees, while the operator should wear rubber gloves and an old suit of clothes. All moss and lichen should be destroyed, also American blight and some eggs of insects.

Strawberry-Beds. If not already done, the soil should be lightly forked over and then a mulching of manure given. Beds that were made last year will not require any manurial assistance.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.).

FOR NORTHERN GARDENS.

The Kitchen Garden.

Onions.—Seeds may now be sown in shallow boxes filled with fairly rich soil and the boxes placed in ainery that has been started or wherever a temperature of 50° to 55° can be maintained. Ailsa Craig and Cranston's Excelsior are excellent for this mode of culture.

Early Leeks.—Where large-sized specimens are required for exhibition purposes by August or September a sowing should be made now. The cultural directions given for Onions are applicable here too. The Lyon and Dobbie's Exhibition are reliable varieties for this purpose. Care should be taken to see that they get no check for lack of water.

The Hardy Fruit Garden.

Winter Spraying. The intelligent cultivator leaves nothing to chance, and winter spraying is regarded by him as a matter of course. Those who have not taken this precaution should do so forthwith, as it pays in the end. Reliable sprays with directions can be obtained from most seedsmen or horticultural sundriesmen.

Gooseberries and Red Currants often get blown out of upright in the earlier stages of their growth. Where such is the case prepare the necessary number of stout forked wooden stakes from tree branches, loosen the soil at the neck of the stem, push the fork against the stem, bringing it upright, then firm the base of the plant and of the stake in the soil by treading.

The Pleasure Grounds.

Rhododendrons.—Large specimens should receive a liberal mulch of farmyard manure or, failing this, half-decayed leaves. This mulch provides the necessary feeding, and will keep the plants cool at the root during the heat of summer. Rhododendron Nobleanum will now be showing flower, and should frost occur it is well worth the while to protect the plants with mats or other suitable protecting material.

The Flower Garden.

Lenten Roses.—These beautiful flowers, if left unprotected, are apt to get injured by sharp frosts. If grown in bulk, they may be protected by means of a temporary framework and mats. Single specimens may be protected by means of a hand-light and a sack, or by a large inverted flower-pot or an inverted box. When cutting the flowers for indoor decoration split the stems up at the bottom about 1 in. to 2 ins. so that they may absorb the water.

Carnations.—Mice are very apt to attack layers in frames when food is scarce. A couple of traps or one or two pieces of Rodine in the frame is a wise precaution.

Pentstemons.—Keep the frames containing these plants well ventilated on all favourable occasions. The plants should be kept rather on the dry side, but do not hesitate to apply water (early in the day) when it is seen to be necessary. The above remarks also apply to Pansies, Violas and the occupants of cold frames generally.

Fruit Under Glass.

Strawberries.—Introduce a batch to ainery or peach-house that has been started, accommodating the pots on a shelf near the glass. Prior to taking them indoors remove all decayed foliage from the plants. Wash the pots thoroughly and remove all weeds, and slightly stir the surface of the soil. Tap the pots to see if they require water, and if so give them a good soaking.

Peaches.—Peaches and Nectarines in flower must receive assistance in carrying through the work of pollination. This can be done either by what is known as the "wet" system or by the

older "dry" system. The "wet" process consists in spraying the trees lightly with a very fine spray about midday, using water of the same temperature as the house. The "dry" process consists in either tapping the trees sharply at the above-named hour or by going over them lightly with a rabbit's tail tied to the end of a long cane.

The Rock Garden.

Top-Dressing.—Most of the occupants of the rock garden are benefited by receiving occasional top-dressings, and, weather permitting, this is a suitable time for applying such a dressing. A supply of various soils to suit the requirements of the different classes of plants should be provided—loam, peat, sand, grit, etc. Free the pockets from weeds and slightly prick the surface of the soil with a handfork previous to applying the top-dressing.

Cutting Back.—Certain plants, such as Rock Roses and Candytufts, are apt to become leggy and to encroach upon their neighbours. Where this has occurred the plants should be cut well back. Other plants, such as the Thymes, trespass by means of root extension; these, too, must be trimmed as much as seems necessary.

CHARLES COMFORT

(Formerly Head-gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

General Work.—If not already done, houses should be thoroughly cleaned, washing the glass inside, also all wall surfaces. The latter should then receive a coat of linewash, using fresh lime for this purpose, adding a handful of flowers of sulphur to every bucketful of linewash. Propagating cases should be emptied and cleaned, replacing old plunging material with fresh. Coconut fibre is now prohibitive in price for this purpose, but I find the next best material is peat moss litter. The bales should be broken up and the litter spread out and moistened, afterwards beating it up with the back of a digging fork and passing it through a quarter-inch sieve, when it is ready for use. This material is clean to handle, lasts well, and, when mixed with some sand, plants root readily in it. All standing material on stages and benches should be renewed where necessary, for it is quite certain that if this is dirty it is harmful to plants. Ashes, coke breeze and such-like should be replaced with fresh. Where pea gravel is used it should, of course, be washed and replaced on the benches. There is not the least doubt that the type of staging used has an important effect on the health of the plants; open sparsed staging, except for a limited number of plants, is nearly always harmful. Slate stagings are good and lasting, but they are nearly always wrongly constructed, being made to take only about 1 in. of standing material, whereas provision should be made for at least 6 ins. It is then much easier to maintain a certain amount of natural moisture on the benches. For this reason there is no doubt that a bricked-in bed filled in with soil or ashes is the best standing medium for plants, as temperature is then more equable and there is always a certain amount of natural moisture present, which is so important for the well-being of most plants. Loam, leaf-soil and sand, a sufficient supply according to requirements, should be kept under cover. Now is a good time to cut and stack loam. Where it can be procured the top spit of old pasture land is best for this purpose. The turves may be cut 6 ins. to 8 ins. in thickness, according to the quality of the soil. Avoid taking it from low-lying situations, as it may be sour from being more or less water-logged. When stacking the turf some lime should be sprinkled between each layer, as old grass lands are, as a rule, very much neglected as regards liming. If it is certain lime is not necessary, then the turf should be stacked with some well rotted farmyard manure.

Seed Lists.—Selections of the seeds required should be made and the order despatched as soon as possible, so that all seeds may be at hand at the required time. Much may be done towards maintaining the greenhouse and conservatory throughout the year by means of plants raised from seed, as most of them flower the same season. Everyone has their favourite flowers and knows their own individual requirements, and while it is wise to trust to well tried plants it is desirable each year to try some new varieties, as it adds to the interest and often results in one finding a plant just suited for his particular purpose. Hardy annuals are now an important feature in greenhouses and conservatories. It is the usual practice to sow the seed during September, wintering the young plants in cold frames or pits.

Where this was done the plants should be ready this month for a shift into a larger-sized pot, and from then onwards until they flower a cool, airy greenhouse is the best place for them. The plants should be neatly staked and kept regularly tied as they require it. Where such plants were not sown during the autumn now is a good time to make a start with them. Some of the most useful are *Schizanthus*, *Clarkia*, *Godetia*, *Lobelia tenuior*, *Mignonette*, *Annual Chrysanthemum*, *Nemesia*, *Rodanthe*, etc. Some annuals, such as *Mignonette*, *Larkspur*, *Rodanthe* and *Acrocloniums*, transplant badly, so they are best sown directly into their flowering-pots. The soil for *Mignonette* should be rammed very hard. A good medium loam is best with some fine bone-meal and dried cow manure added to the compost. The compost is best without leaf-soil, and as lime in some form is essential, some old mortar rubble may very well take the place of sand. *Mignonette* is by no means easily grown in pots, and requires all the skill and care one can give it to obtain good results.

Grevillea robusta is very popular for decorative work, and seeds should now be sown. This sowing often proves a failure; true the seeds may sometimes be bad, but failures are nearly always due to sowing the seeds flat, for being very thin, many of them rot. Successful germination can generally be obtained by standing the seeds on edge in the compost.

Royal Botanic Gardens, Kew. J. COULTS.

BOOKS

Our Birds.—Two little books* came recently to hand for review with attractive pictures on their otherwise uninteresting green paper covers. The proportioning of the books is not very happy—the pages are almost square, but the pictures of birds, their nests and young are admirable. The illustrations are the main feature of both little volumes, each picture being faced by a brief but quite vivid account of the bird or nest illustrated. "First Series" includes all birds whose English names begin with the letters A to O, and "Second Series" the remainder. These should be very useful little books for giving boys and girls an insight into the bird-life of this country. Even "grown-ups"—and not always town-dwellers at that!—are oft-times none too certain of the identity of the less common kinds. It is perhaps a pity that the Latin names of the species are not included with a key shewing the grouping of the genera. After all, knowledge is better systematised.

The late Mr. S. T. Wright.—The Council of the Royal Horticultural Society has subscribed £100 towards the fund which, on its initiative, is being raised to commemorate the late Mr. S. T. Wright's long and devoted services to horticulture and to the Society, and to provide much needed assistance for his widow. The subscriptions to the fund already held by the Royal Horticultural Society amount to nearly £170, and there can be little doubt but that the late Mr. S. T. Wright's many friends who have not already subscribed to the fund will be glad to add contributions, which will testify both to their enduring regard for the man and their appreciation of the services which in many ways he rendered to horticulture. To walk round Wisley Garden with Mr. Wright was a liberal education. He knew every plant and loved them all. Few men have had a larger opportunity of helping professional and amateur gardeners, and none has availed himself more fully of that opportunity. Mr. Wright's work in the service of the Society extended over many years, both at Chiswick and at Wisley. Although a frugal man, it was not in his power to make full provision for his widow and children. We believe that, thanks to the pension scheme inaugurated by

the Royal Horticultural Society, and also to savings made by Mr. Wright, some provision is already made for Mrs. Wright. Nevertheless, the fact remains that without further assistance life will be made very difficult for her. It is the hope of her husband's colleagues and friends that Mrs. Wright may be relieved of all financial cares, and they confidently believe that all that is needed to secure this end is to bring the knowledge that help is needed to all sections of the horticultural community. Subscriptions should be sent to the Secretary, Royal Horticultural Society, Vincent Square, Westminster, S.W.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

MONTBRETIA NOT FLOWERING (D. B. Abyssinia).—In Britain *Montbretia* are grown successfully in chalky districts and others that contain little lime. There is no reason why old mortar rubble should not be employed by way of experiment, but our impression is that the failure occurs when the moisture in the soil fails. We have a recollection of them becoming brown from the tips of the leaves downwards, just when they were preparing to bloom. This was in a chalk district, liable to get dry in summer, and to overcome this the corns were afterwards planted on the shady side of trees, after which the leaves did not get browned. In another gravelly garden they were planted on the shady side of trees, just far enough away to be out of heavy shade and clear of tree roots. The soil was somewhat peaty and cool. We would suggest that well decayed horse manure or half decayed leaves be used and put some inches below the corns to hold moisture. Water should also be given liberally when the spathes are well above ground. They should be transplanted as soon as the foliage dies away and the corns of flowering size given plenty of room. Perennial *Lupinus* certainly like plenty of moisture so that horse manure would benefit them and could be dug in during the resting season. We would suggest that our correspondent rears them from seeds and plants them in their permanent positions while quite young.

ROSE GARDEN.

SINGLE ROSES FOR NORTH ASPECT ("South-facing").—Most, or all, Roses, single and double, like sunshine best, but a few are known to give satisfaction on a north aspect. *Rosa Hugonis* and *R. lucida* are too wary in growth to succeed under a north aspect wall, unless very low. *R. lucida* rarely exceeds 2ft. to 3ft. in height, and that would be a disadvantage to it. Tall bushes that get sunshine over the top of the wall are more satisfactory, so if the wall is low many single Roses would succeed. Conrad F. Meyer is known to succeed on north and south aspects, but that has got Dijon blood in it. All the same, we would recommend the single *Rosa rugosa* alba (white), *R. atrorubra* (blackish crimson) and *R. r. rubra* (rose, shaded violet). *R. Wichuraiana* (white), *Blasvatha* (crimson) and *Evangelina* (white, tipped pink), the latter two *Wichuraiana* hybrid, are likely single-Roses for the situation. The *Ayrshire* Roses would be suitable, but the cultivated varieties are double or semi-double.

TREES AND SHRUBS.

SHRUB FOR A HEDGE (N. S. C.).—*Berberis stenophylla* is an excellent evergreen shrub, suitable to form a hedge. It has rich yellow flowers. This shrub is quick growing, thrives in nearly all soils and forms a thick, impenetrable screen. Early April is the best time to plant, but planting may be done successfully in January. An alternative for a hedge would be the Japanese Rose, *Rosa rugosa*, but this cannot be pruned so closely as the *Berberis*.

The "PERFECTOR" ARCH forms an ideal setting for the Rose Garden. The man whose pride is in his Garden will appreciate the simplicity and effectiveness of this design. The construction is light, yet strong enough for a permanency, being specially designed for the cultivation of climbing Roses, Clematis, etc. It is made entirely of OAK and treated with Solignum, size 7 ft. high above ground level, and 3 ft. 4 in. wide inside. **Price £1 each.** Orders for three or more will be sent Carriage Paid. Cash with order. These can be made wider than 3 ft. 4 in. if required, prices for which will be quoted on application, stating number required.

THE "PERFECTOR" PERGOLA.

This is constructed with the above Arches spaced any distance up to 6 ft. apart. The longitudinal and secondary cross bars to complete the Pergola are supplied in OAK, treated with Solignum, at 1/6 per foot run of Pergola; any lengths to suit your requirements. Thus the price of the Pergola illustrated, 25 ft. long, works out as follows:—

4 Arches at £1 each	£4 0 0
25 ft. run Top Bar at 1/6	£1 17 6

CARRIAGE PAID .. £5 17 6

"Prepare for the Spring."

Be ready this year for the cold winds and frosts which take toll of your seedlings, young plants and fruit crop, unless you take steps to keep them off.

WINDOLITE

will do this at a cost that will be repaid by the extra yield of the first season's crop.

"Windolite," like glass, keeps out cold and wet, but lets in light, whilst plants thrive under it. Unlike glass, however, "Windolite" can be bent, but not broken, can be cut with scissors and fixed easily to the lightest of framework.

With "Windolite," no skilled labour is needed in making cloches, screens and hand-lights of any size or shape, which in use are strong, light and handy, but, when not wanted, can be put away without fear of damage.

If your local dealer does not stock, we shall be pleased to send any length from one yard upwards post free, on receipt of cost.

Beautiful Winter Flowers

at Reading.

SUTTON'S PRIMULAS AND CYCLAMEN.

No other flowers can equal our beautiful Primulas and Cyclamen in making—during this season of the year—a lovely show of bloom in almost every colour, at a moderate cost.

During the next few weeks we shall have a particularly fine display in our glass-houses at Reading. Our Experimental Grounds in which these houses are situated adjoin the Great Western Railway, about two miles east of Reading Station, on the Great Bath Road. All interested in these beautiful flowers are invited to visit the houses while the display is at its best.

Complete descriptive lists of all the best varieties will be found in Sutton's Garden Seed Catalogue for 1923, FREE.

SUTTON & SONS, The King's Seedsmen, READING.

[JANUARY 20, 1923.]

THE GENUS COTONEASTER

The introduction of new Cotoneasters from China during recent years has more than doubled the number of species and varieties in cultivation, and added considerably to their value for garden and open woodland.

THE Kew Hand-List of Hardy Trees and Shrubs, published in 1902, enumerates twenty-three species and four varieties of Cotoneasters. The Kew collection at the present time contains fifty species and twelve varieties, and in addition a number of Chinese introductions still under the collectors' numbers. While it cannot be claimed that all are valuable and distinct shrubs or small trees for general planting, it would be quite easy to pick out twenty-five and dilate at considerable length on their value as lawn specimens, for massing or open woodland planting, for the shrubby border, for rock garden or sloping banks.

Both deciduous and evergreen shrubs are represented in the genus, while others may, perhaps, best be described as sub or semi-evergreen, for while some of the leaves may hang on until the spring during a mild winter, hard frosts in November or December soon clear the bushes. Again, it is noticeable that the leaves persist on the bushes in damp positions and heavy soils longer than on dry, well drained slopes.

In habit Cotoneasters are very variable, ranging from the prostrate *C. Dammeri* to *C. frigida*, which at Monreith grows 30ft. to 40ft. high. Cotoneasters are very easy shrubs to accommodate as regards soil. Excluding bog land they thrive in practically all soils one is likely to meet. Seeds, cuttings and layers provide ready and rapid methods of propagation. Vegetative increase is the best and quickest, for not only do Cotoneaster seeds sometimes remain dormant for a time in the soil, but seedlings are apt to vary, not always to the advantage of the grower. On the other hand it must be admitted that seedlings sometimes lead to improved varieties.

SELECTIONS OF THE BEST SPECIES.

For Flowers.—*C. multiflora*, *C. frigida*, *C. turbinata*, *C. salicifolia* and varieties, *C. pinnosa*.

For Fruits.—*C. frigida*, *C. rotundifolia*, *C. Simonsii*, *C. salicifolia* and varieties, *C. Francheti*.

For the Rock Garden.—*C. Dammeri*, *C. adpressa*, *C. microphylla* and vars. *glacialis* and *thymæfolia*.

C. adpressa.—In some respects this Chinese Cotoneaster resembles *C. horizontalis* (q.v.), and is described by Schneider as a variety of that species. In our gardens, however, the growth is quite distinct. To begin with it is a smaller growing plant, the branching is irregular (whereas in *C. horizontalis* it is regularly distichous), the leaves are

thinner and the subglobose fruits are larger. *C. adpressa* is spreading or prostrate in habit, plants 3ft. in diameter being only about 1ft. high. It is thus an ideal hardy shrub for the rock garden, growing over boulders and ledges. A deciduous species, the small flowers are white, tipped with rose, and the fruits red, subglobose, about ½ in. long. *C. adpressa* was first introduced to France about 1895 by a French missionary, and again from Western Szechuan by Mr. E. H. Wilson in 1908 and 1910.

C. AMENA.—This is an evergreen species and was first introduced from China by Mr. Wilson when collecting on behalf of Messrs. James Veitch and Sons during 1904 in Yunnan. It is a freely branched shrub up to about 6ft. in height, allied to *C. Francheti*, but of more compact habit and smaller leaves. The small white flowers are freely produced in corymbs of about six to ten flowers, followed by rich red fruits. This is a very good bush for the wide shrubby border and where the pleasure grounds merge into the woodland.

C. BACILLARIS.—A large deciduous bush or small tree, 18ft. to 20ft. or more in height, this Cotoneaster is a conspicuous shrub in the Queen's Cottage grounds and by the lake side at Kew. The white flowers are only ½ in. in diameter, but being very freely produced in cymes *C. bacillaris* is a showy flowering bush. Though not attractive at a great distance because the fruits are dark purple, they are very freely borne and long sprays are useful to cut for vase decoration with coloured autumn foliage. This species is a native of the Himalayas, being found up to 10,000ft. The natives value the wood for making walking sticks, and being strong and elastic its use for golf clubs has been suggested. Its robust habit makes *C. bacillaris* of considerable value in large shrubby borders, by the waterside, for plantations and in open woodland planting.

C. BULIATA.—This is a tall, deciduous species of more open growth than most Cotoneasters, 6ft. to 15ft. or more in height. It is a native of China and

THE TRAILING RED BERRIED COTONEASTER DAMMERI RADICANS.

Tibet, coming to us first by way of France, through the French Missionaries and M. Mamie de Villemor in the late nineties. The rosy white blossoms are not conspicuous, but the value of *C. bullata* lies in the rich red fruit. 2 in. to 4 in. in diameter, which, in seasons, are very freely borne. A large leaved form of this species, var. *macrophylla* (No. 873, Wilson), was collected by Mr. Wilson in Western Szechuan in 1905. *C. bullata* has been confused with *C. monquensis*, but that species is readily distinguished by its black fruits.

C. LUXIFOLIA. Until the introduction of recent date from China this was the tallest growing and best of the truly evergreen Cotoneasters. The average height is 8 ft. to 10 ft. or 12 ft. It has, generally, long and slender branches, clothed with dark green leaves up to 4 in. long. The clusters of small white flowers are succeeded by quantities of rich red fruits. In addition to its value for large grouping or massing in the pleasure grounds and for the shrubbery border, I have seen this *Cotoneaster* planted most effectively as an informal hedge or dividing line between the garden proper and the woodland. *C. luxifolia* was first introduced from the Neelgherry Hills in 1824.

C. DAMMERI. This very distinct prostrate-growing *Cotoneaster* is better known in British gardens as *C. humilis*, for this is the name it was given at Kew when introduced by Mr. Wilson, and first disseminated by Messrs. James Veitch and Sons from their Coombe Wood nursery. It subsequently proved to be identical with the plant previously named *C. Dammeri* by Schneider. Keeping quite close to the ground, in habit it is distinct from any other species. Free in growth, the plant spreads rapidly, rooting in the ground as it spreads as does *Yucca*. In the rock garden the long trailing evergreen shoots are very effective hanging over boulders and ledges of rock. *C. Dammeri* var. *radians* is similarly prostrate in growth, Mr. Wilson distinguishing it from the type in having longer peduncles and pedicels, with constantly one or two flowered racemes. Mr. Wilson collected the type (No. 481, W.) in Western Hupeh and the variety *radians* (No. 1071, W.) in Western Szechuan.

C. DIETSCHIANA. Here again we have a plant with two names, *C. applanata*, Duthie, and *C. Dietschiana*, Prtzel, the latter being the first and thus the accepted name, though *C. applanata*, descriptive of the distichous branch arrangement, is obviously the better name for the plant. It is an open, free-growing bush of light and elegant habit with arching branches. *C. Dietschiana* is deciduous, not noteworthy in blossom, but gay with scarlet fruits in autumn. A native of Central China, it was first introduced by Mr. Wilson in 1910.

C. FRAXINIFOLIA. This is a widespread evergreen shrub 8 ft. or more in height and as much in diameter. The corymbs of small white blossoms, often eight to a dozen or more together, are followed by showy orange-scarlet fruits. It is one of the best known Chinese species, especially in France, where it was first raised about 1805 from seeds sent by the Abbe Soulie. In the shrubbery border and the open woodland *C. Franchetii* is worthy of attention by planters.

C. LINDLEYANA. This is the most decorative and valuable of all the vigorous growing deciduous *Cotoneasters*. Though usually seen as a widespread bush 10 ft. to 20 ft. or more in height, it readily forms a trunk, and makes a beautiful specimen lawn tree of fair size. Sir Herbert Max well, writing in *The Garden* of July 24, 1920, describes self-sown seedlings of this kind in the woods at Monmouth between 10 ft. and 10 ft. in height, the trunk of one specimen measured 2 ft. 12 in. at 1 ft. from the ground. In flower during June the flatish corymbs of white blossoms are distinctly showy. It is, however, in autumn and winter, when the branches are weighed down with the large clusters

BRILLIANT BERRIES OF *COTONEASTER FRIGIDA*.

ONE OF THE "SAILS" OF *COTONEASTER HORIZONTALIS*.

GLOSSY EVERGREEN FOLIAGE AND DEEP CRIMSON FRUITS OF *C. BUXIFOLIA*.

EAST LOTHIAN STOCKS

Early Sowing Ensures Summer Flowering.

of red fruits, that *C. frigida* attracts most attention. It is not surprising that a shrub so readily raised from seed should be improved by selecting free-fruited and richly coloured forms. Earham variety was recently given an award of merit by the Royal Horticultural Society. The var. *Vicari* raised at Aldenham House, and var. *montanum*, which we obtained from the late Mr. T. Smith's nursery at Newry, are also noteworthy for the abundance and bright colour of the fruits. There is also a yellow fruited variety, *fructu-luteo* which opens up possibilities of raising golden yellow-fruited *Cotoneasters* by seedlings and selection. *C. frigida* is particularly valuable as a town shrub.

C. HARROVIANA.—An evergreen bush of spreading rather than upright habit, the small white blossoms are showy and freely borne in axillary and terminal corymbs. These are followed by red fruits which hang on bushes into the New Year. Mr. Wilson introduced this *Cotoneaster* from Yunnan in 1899. Attractive in flower and fruit it is worthy of a place in the pleasure grounds and shrubbery borders, where it forms an effective screen throughout the year.

C. HENRYANA.—This is one of the largest-leaved evergreen *Cotoneasters*. Individual specimens are not particularly attractive because of a loose and more or less pendulous habit unless restricted at first to a single stem. Shapely specimens obtained by a little judicious pruning each year in spring make good lawn plants. A group of six to a dozen or more bushes in a shrubbery border or massed in the pleasure grounds has a good foliage, effective with quantities of white flowers in June, followed by an abundance of brownish-red fruits. When first introduced by Mr. Wilson from China in 1901 this *Cotoneaster* was grown as *C. rugosa* var. *Henryi*.

C. HORIZONTALIS.—In several respects this is one of the most distinct and beautiful *Cotoneasters*. In the open it forms a low spreading bush some 2ft. to 3ft. high, but against a wall it will grow very much higher. A plant in such a position at Kew, 10ft. high, was illustrated in *THE GARDEN*, December 17, 1904. Its value as a low shrub for sloping sunny banks was also illustrated in *THE GARDEN*, December 4, 1920. Though strictly deciduous in mild winters, many of the leaves remain on mid way through the winter. It has flat fan-like spreading branches, a characteristic which has caused it sometimes to be spoken of as the fish-bone *Cotoneaster*. It has no claim to floral distinction when the small pink-tinted white blossoms open early in June, but during autumn the neat glossy green leaves and bright red fruits give it a very attractive appearance. Later, the leaves develop a bronze tint, changing in turn to red and crimson. We are indebted for the introduction of this useful *Cotoneaster* to the Abbé David in 1885.

C. INTEGERRIMA.—This shrub is of interest, being the only *Cotoneaster* found truly wild in Britain, its other name of *C. vulgaris* being, perhaps, better known to students of the British Flora, who know of its existence on the Great Orme's Head. *C. integerrima* is also found wild in Northern Europe, Persia, Siberia, Tibet, Manchuria and Northern India. Growing 5ft. or 6ft. high it is a deciduous shrub, usually with red fruits, but there is also a form (var. *melanocarpa*) with black fruits.

C. MICROPHYLLA.—A low-growing evergreen shrub of graceful habit, this is a favourite shrub for the rock garden, low walls, sloping banks and the fronts of shrubbery borders. In autumn the small glossy green leaves are thickly interspersed with small red fruits. It is a native of the Himalayas, being a common shrub at from about 4,000ft. to 11,000ft. elevation. The first record of its introduction appears to be 1827, when the East India Company sent seeds to the Royal Horticultural Society.

(To be continued.)

A. O.

THESE beautiful and free-flowering Stocks are not nearly so popular in England as they are in Scotland. Yet they do equally as well if given good treatment. It is rather invidious to compare them with the Ten Week Stocks, for both have outstanding merits and both should, in my opinion be grown in every garden, but I do think that they are better bedding plants and give far more flower. On the other hand there is greater variety of colour and also, I believe, a more decided fragrance with the Ten Week Stocks.

In the ordinary way the East Lothian Stock may be regarded as an autumn or a late summer flowering plant, but by sowing the seeds in January or February and getting the plants forward, they may be induced to commence flowering in June and retain flowers till late in the autumn.

I first grew these plants when I was in Scotland some twelve years ago and was struck by their beauty and their prodigality of flowering. On my return to England I grew them again and giving them better treatment I succeeded far better with them. The seeds are sown late in January or early in February in a pan of sandy soil in the usual way in a warm temperature. Under ordinary conditions germination is seen in about a week's time and, usually, in another week the seedlings are ready for pricking off. I find that early pricking-off is a safeguard against damping, and I am particularly careful not to put the seedlings where the spray of the syringe will reach them. As space in the greenhouse is precious at this time of the year, and as the seedlings will not remain long in the box, I prick them off at 2ins. apart. They are left in the boxes for rather more than a month, by which time there is a tendency to crowd. As it is particularly desired that the plants should do well, they are then potted singly into 3in. pots and are kept growing steadily along in full sunshine and close to the glass until they fill the soil with a network of roots. This brings us to about the third week in April. The final potting should not be delayed longer, else the plants will not have well filled the pots with roots by planting-out time. At this stage I have removed them to 6-inch pots, but better results were obtained when only 5-inch pots were used, and it is a better size from which to plant.

From this time onward they should gradually be inured to outside conditions by ventilating freely and later removed to a cold frame, where the ventilation can be gradually increased until

they have attained that degree of hardiness which will justify their being planted out towards the end of May.

Dates, of course, are only a guide, and in that light only I append the following details from my diary:—

January 20.—Seeds sown in a pan of sandy soil in warm greenhouse
 „ 28.—Seedlings appeared above the surface.
 February 3.—Seedlings pricked off closely in a box

A SPIKE OF EAST LOTHIAN STOCK.

March 14.—Young plants potted singly in 3in. pots.
 April 20.—Moved along to 5in. pots.
 May 26.—Planted in the beds.
 June 1.—Flowering commenced and continued till
 October 23.—When the Stocks were removed and the bed prepared for spring-flowering plants.

The beds in which these plants were grown were always bastard-trenched and manured once a year, usually in autumn. Beyond that no special cultivation was afforded. In course of time the plants spread so as to be quite 18ins. through. A central flower spike developed first and on many of these the actual flowering part measured a foot. When this faded it was removed and was succeeded by numerous side flowering growths. On one of the best plants I once counted fifty-three of these and in no plant could I count less than thirty. This development surely justified the extra care devoted

to the plants in their early stages. There is, of course, the difficulty that some plants shew single flowers, but this I overcome, first of all, by buying only first class seeds and, secondly, by keeping a reserve of plants in pots, so that singles can be removed and replaced by plants already

showing double flowers. If these Stocks are planted in a sheltered position not otherwise needed they can be left through the winter. Some of them doubtless will not survive the ordeal, but those that do will give an abundance of flowers in late spring. W. E. R.

MOSSY SAXIFRAGES

THE Mossy Saxifrages that is those belonging to the *dictyoides* section are a little looked down upon by real alpine plant fanciers because of their ease of culture and

a noticeable coarseness of "finish," which distinguishes the bulk of them. This coarseness is chiefly noticeable when one compares them with tufted (*Kalschian*) treasures. Actually, the Mossy

SAXIFRAGA GUILDFORD SEEDLING, STILL ONE OF THE BEST CRIMSON "MOSSIES."

VIGOROUS GROWING AND HANDSOME, *S. BATHONIENSIS*.

section provides more real effect in the garden than the tufted sorts can hope to do. Most of the desirable sorts are of hybrid origin or greatly improved forms of species of comparatively small garden worth—in short, practically florist's flowers, which also does not endear them to the enthusiastic alpine collector.

Nowadays, the red-flowered forms are fashionable, probably because new deep-coloured varieties are continually being raised and sent out. This notwithstanding, the best Mossy Saxifrage is unquestionably a white one, *S. Wallacei*. The origin of this is quite uncertain, though to the layman it looks to have *trifurcata* blood. It has a double claim to pride of place: the beauty of snow-white blossom—which, though incomparably finer, always reminds one of that of the rampant but beautiful *Sedum album*—and beauty of foliage. *Saxifraga Wallacei* provides the most beautiful green carpet of any rock plant in cultivation. A group of plants quickly runs together and forms a solid and beautiful mat, so compact and so firmly inter-rooted that it may be lifted as a whole and exhibited entire many miles away!

Saxifraga trifurcata has already been partly described in that *S. Wallacei* was said to "take after" it. The rosettes are formed of three parted leaves, which are much stiffer and more rigidly held than is usual in this section. The variety *ceratophylla*, the Stag's-horn Saxifrage, has the leaves more deeply parted, more glaucous and more rigid than the type. It is also rather larger in the rosette. Both are white flowered and cover themselves with blossom. As one might expect from the foliage, neither needs nor likes quite so cool and damp a situation as suits the generality of Mossy Saxifrages. *S. canaliculata* is nearly related, being similar to *S. trifurcata*, except that the leaves are a softer (less blackish) green and also less rigid. *S. Camposi* as usually sold in nurseries is *S. Wallacei*. The true plant, however, is a species of much smaller growth and smaller blossoms on rather tall stems. *S. cuneata* is a comparatively large grower with deeply cut three-lobed foliage and white flowers, less abundantly borne than with most of the kinds mentioned. *S. Maweania* is a North African and is noteworthy as a deciduous Mossy Saxifrage. It makes trailing stems which, when devoid of foliage, remind one rather of a strange *Sedum* than a Saxifrage. The new foliage when it breaks into leaf is a very beautiful green and the developed rosettes are handsome enough. The white flowers are of good size and freely produced. It should have a warm, sheltered corner with, if possible, the shelter of a overhanging rock, as it is not over-hardy.

S. caespitosa is a variable species with white flowers. A quick grower it, or the nearly related *S. decipiens*, is a parent, or rather an ancestor, of all the large-flowered coloured "Mossies" in cultivation. *S. decipiens* is very similar but larger habited. The red in the hybrids was originally obtained from the charming carpeter, *S. muscoides atropurpurea*. *S. Guildford Seedling* was the first of these hybrids and it is still one of the best, though not so strong a grower as some. The variety called *sanguinea superba* is one of the best red-coloured ones to date. Another admirable sort is called *bathoniensis* or sometimes, stupidly enough, *decipiens grandiflora*. There are a host of others, most of them with "blood" of the Meadow Saxifrage, *S. granulata*, but many of them are coarse habited and the flowers fade badly and are very ugly when faded.

There are many others of the *caespitosa* kin often catalogued, some of which, if not all, are, rightly speaking, forms of *caespitosa* or *decipiens*. Such are *SS. Iratiana*, *nevadensis*, *gröenlandica*, *quinquenda*, *Sternbergii*, *Steinmanni* and *sponheimica*.

S. muscoides atropurpurea has already been referred to as the colour-bearing parent of the red-flowered hybrids. It is a natural variety or subspecies of *S. muscoides* and bears greenish yellow flowers which closely stud the tight carpet of miniature rosettes. There are other natural varieties besides *atropurpurea*. Such are *crocea*, with flowers yellow than the type; *pygmæa*, even smaller than the species; *Allionii* and *densa*. For smothering damp rocks or forming a close sheet of verdure in a cool position on the rockery,

THE VERY VARIABLE *SAXIFRAGA CÆSPITOSA*.

S. muscoides and its forms are invaluable. *SS. planifolia*, *sedoides*, *Segueri*, *aphylla* and *androsacea* all belong to the *Muscoides*—the subsection of which *S. muscoides* is the type plant.

Larger growing than the plants of the section just mentioned, but still a dwarf, is *S. hypnoides*, "Dovedale Moss," as it is often called. The brightness of its emerald carpet is one of its chief attractions. In winter *S. Wallacei* is, indeed, its only rival, but it is, of course, an altogether smaller grower than that fine kind. An exceedingly easy "doer" and of rapid growth, it forms an excellent cover for the many bulbous plants which are suitable for the rock garden. The flower stems reach a height of 6 ins. or more and the white blossoms are produced in great abundance. There is a compact variety called *gemmifera*, while for those who like such things there is a silver variegated form. As its English name would suggest, *S. hypnoides* is a native of our own Derbyshire and Yorkshire highlands.

Unless otherwise noted, all Mossy Saxifrages like a fairly well drained, but moderately damp soil in a cool (north-easterly or north-westerly) aspect. They resent drought.

QUITE apart from its great beauty, as the boldest and most notable of our native evergreen climbers, Ivy can be put to a wide variety of uses in both town and country gardens. It is obtainable in an extraordinary number of forms, or varieties, and so variable is it in the wild state that anyone in a locality where it abounds might gather half-a-dozen widely differing types in a morning's walk.

In our own woodland garden, a great part of which is a rather sharp slope, this plant is extensively employed for covering the ground, thus not only serving as a carpenter, but as a means of holding the loose, trickling soil in place. Grown in this way—and most of it has appeared naturally—the Ivy slope looks delightful at all seasons. It seldom needs any attention, yet the mat is never too dense to allow Snowdrops to push through it in spring. These are followed by Narcissi, Lily of the Valley, Anthericum, Montbretia, Schizostylis and many other things of the kind. It does not interfere with the welfare of various native and other Ferns and it helps to keep the ground cool for a number of shrubs. These last have at times to be cleared about their roots, since it is the habit of Ivy to ascend any support it comes in contact with, but we have found that, once they are established, such kinds as Rhododendron, Azalea and Broom and, indeed, the majority of shrubs grown in the semi-wild garden will hold their own against the Ivy carpeting.

Ivy is also an excellent plant for covering the ground beneath tall trees, such as evergreen Oaks or conifers, which is often denuded of all vegetation. It can be seen planted in this way at Kew and in many other public and private gardens where it makes a rich green carpeting which demands a minimum of attention. For this purpose and that indicated in the preceding paragraph I do not think there is anything better than a good form of the wild plant.

Remarkably neat edgings can be produced with choice Ivies, whether these are trained over stone or simply grown in a line as a tiny hedge and kept close by pinching or trimming, especially in spring. In some gardens and parks this plant is utilised on verges more freely than merely as an edging. That is to say, it is planted and trained in belts or wide areas, thus taking the place of turf, which is very much more costly in upkeep. In this way a ground covering of Ivy kept to a uniform thickness of about 6 ins. proves to be an admirable setting for almost any ornamental shrubs or plants. As for wear, it will be found remarkably tough and

quite serviceable enough to withstand anything but regular, daily treading. Such Ivy belts as these only need shearing once or, at most, twice a season, the work does not entail much labour and the trimmings can be left to settle into the bed along with the natural partial leaf-fall of the plant in spring.

Though Ivy will climb 40 ft. to 50 ft. and more, when ascending a tree or ruin, before commencing to flower, it will often go as many yards on the flat. As a matter of fact, one may take it that there is no limit to the distance to which Ivy will creep, for it roots as it goes along and will continue doing so provided it is not checked and that suitable conditions exist. The object of this creeping is doubtless that of discovering some vertical object up which the plant can climb, flower and set seed; but no one can tell what the height is at which *Hedera Helix* may be said to reach its full stature and become fruitful, for in one place it will be in maturity when only 3 ft. to 4 ft. high and at another it will still be in course of development though it has ascended to ten times that height.

As for the various uses to which Ivy can be put as a covering for walls, these are so familiar that one need not dwell upon them. I may say, however, that this hardy old climber will stand a town atmosphere, shade and draught better than most climbers, and if properly cared for, may be used on walls which are intended to be attractive in summer. Many of the Clematises, for example, will climb an Ivy wall, and nothing looks better than scarlet ropes of *Tropæolum speciosum* when trailing over the deep, glossy green of Ivy. *Eccremocarpus scaber*, "Morning Glories," and several other rapid climbing plants will also come to mind as suitable plants for similar company.

Tree-stumps and other unsightly things, often difficult to dispose of, can be made delightful with a covering of Ivies, and in such places a collection of the finer, more "fancy" kinds can be interesting as well as beautiful. A "stumpery" with a covering of any good form of the wild Ivy and some native Ferns also, makes a first-rate setting for the Flame Nasturtium, *Arenaria montana*, *Convolvulus althæoides* and various other plants.

I have suggested the wild Ivy for most of the above purposes because it is more generally useful and is a better doer than the coloured or variegated varieties, which need—and perhaps deserve—rather more considerate treatment; but there are also a goodly number of distinct, named kinds which possess quite enough vigour for most purposes. The Tree Ivy also deserves notice since it makes an imposing mass, or pyramid, of green which is goodly to look upon at any season, whether in the woodland, shrubbery or as a formal specimen on the lawn.

Lastly, though I do not presume to have done more than offer a few suggestions as to the uses of "the Ivy green," there is the question of the Ivy-clad tree. I am not going, however, to discuss the pros and cons of Ivy as a tree-creeper, for the subject is a wide one and everything depends upon the quality, nature and uses of the trees concerned, as to whether Ivy should or should not be permitted to embrace them. In so far as we are concerned, Ivy is permitted to do as it likes with several of the old Oaks of our woodland garden. Such trees could hardly be put to better use, for the Ivy, though beautiful at all times, is not less attractive when its bright, glossy green begins to shew in vivid contrast to the warm russet and buffs of autumn, than it is to-day, when it lends an additional interest to the naked trees and does no little service as a wind-break.

N. Wales.

A. T. J.

COMMON ERRORS IN VINE CULTURE

MANY papers have been written by myself and others on what to do in the vinery. I now propose to offer a few remarks on "what not to do." Many people aim at getting very robust growth on young Vines. They encourage the growth above ground with the idea of getting strong, healthy roots, and only a few years ago it was a common practice to allow young Vines to run wild for one or two seasons and cut them down in autumn or winter. I am afraid the practice is not yet obsolete, for only a few weeks ago I received a letter from a gardener in charge of a very important place complaining that his young Muscats had done badly; they had made hardly any growth and the foliage was bad. This was a great disappointment after the promise they had given the year before.

Now it so happened that I had samples of the growth of these Vines the previous year, and the grower was very proud of them. They were three-quarters of an inch in diameter, but the buds were not so prominent nor so regular as some under my observation, the wood of which was not more than half that size. We must expect the growth of the roots to correspond in some measure to the top growth, and my experience with large, fleshy roots is that they do not ripen, and to a great extent die back in winter. Of course the root hairs by which the roots feed are annual only, and should always die back, but the fibrils on which these root hairs are produced should not do so.

One should be careful in making a new Vine border not to use too much nitrogenous matter.

When I can procure good, turfy loam of medium texture, containing a fair amount of fibre, I use no nitrogenous manure with it, but only phosphates, potash and lime rubble. There must, however, be something to decompose in order to render the soil fertile. If there is a good quantity of grass roots, this will be sufficient for a year or two, but in the absence of such roots a little strawy manure is advisable, but it should be used sparingly. Naturally, when the soil is likely to become partly exhausted, after the Vines have come into bearing, feeding must be done.

Borders are frequently made too deep. From 2ft. to 2½ft. is ample. The friendly bacteria, so important in the preparation of plant food, scarcely exist at a much lower depth, nor aeration, another important matter.

Outside borders are frequently made sloping. I prefer them level, so that watering, whether natural or artificial, is more likely to be regular. It is also essential, whether the Vines are planted inside or out, to know where the roots are. Bricks and mortar will not confine them. I have seen borders, both inside and out, carefully and regularly watered when they did not contain a single feeding root, these being 30ft., 50ft. or more away. It is well, therefore, before the Vines have been planted half a dozen years to cut a trench, say, 6ft. away from the stems and sever any straggling roots. If the Vines are planted inside the house, it is wise to examine outside occasionally, even if there is a gravel path, to see whether any roots are there. When roots do get outside the place so carefully prepared for them, they seem to prefer the unprepared ground. It was a common practice—I do not know if it is so now—to unfasten Vine rods and bring the upper ends down as low as possible in order to make them break more regularly. I may say I have never practised it, and when I learned that they would grow upside down as well as the ordinary way, I was convinced that bending down was unnecessary.

As to the syringing usually given when they are required to start, what is it for? The idea seems to be that it causes the rods to break more regularly and quickly. Now both the rods and the buds before the latter start into growth are impervious to water. The buds have layers of protective scales over them, and they need it considering the barbarities practised on them! As for the rods, if you cut a length, seal up the wounds and place it in water for a week, it will be just as dry under the bark as when you placed it there.

Then as to syringing after growth has commenced what is that for? To keep down red spider, I am told. Well, I have had as many as

eight vineries belonging to seven different persons under my superintendence and only in one place did red spider appear, and this was a new charge where the insects had not been exterminated in the winter. I have never syringed Vines in my life except when applying an insecticide or fungicide. The evils of syringing and too much damping down are many and great, while those who practise it regularly are not always free from red spider. Leaves grown in an atmosphere which is too damp are not so perfect as those produced under more rational conditions.

Dr. Masters says in "Plant Life": "It has lately been shewn by M. Vesque that the leaves are both thinner and longer than when grown in dry air, that the vascular bundles of the stem are also thinner and less perfectly developed than in dry air." I do not advise a perfectly dry atmosphere for fruit growing, but I do advise moderation. We see inside Vine borders coated with moss and lichen, yet the damping is continued. There are times when damping is beneficial; for instance, in the early part and middle of a very hot day, while the ventilators are open and there is danger of the temperature rising too high, but in dull weather, excepting in a forcing-house with strong fire-heat, it is not only unnecessary but harmful. Houses under my charge have frequently gone a week, even in summer, without damping. I like the surface soil to become dry sometimes if the roots are inside, so as to admit air to them and also to prevent the soil becoming sour. Damping immoderately at closing time either the soil or the leaves is barbarous; it checks transpiration and consequently hinders feeding by the roots.

Here is another point. I have seen Vine and other leaves droop in the early part of the day after ventilation has been given, when there was no apparent reason to the casual observer. This I attribute to the atmosphere having been too moist. We know that in their struggle for transpiration in a saturated atmosphere the stomata will open to their fullest extent. If, when this condition prevails, one opens the ventilators only a very little, much of the moisture will rapidly escape before the automatic machinery of the leaves has had time to accommodate itself to the changed conditions. You may see the same thing take place naturally in the case of Potatoes and even the Brassica family when sudden sunshine bursts out after a wet spell.

We cannot prevent Potatoes suffering in this way, but we can Vines! Wm. TAYLOR.

APPLEY TOWERS GRAPES AS GROWING.

A CHARMING BORAGEWORT

To those who have failed with such "miffy" charmers as *Mertensia virginica* may be recommended the hardly less lovely and much more accommodating *M. sibirica*. Though often listed among peat, even bog, plants this hardy perennial will flourish in any good border soil that is not too hot and dry. Once established, it will take care of itself for many years, coming up with refreshed vigour every spring after having died back to the base the preceding autumn. *M. sibirica* sends up shoots about 2ft. or more in height from a moderate-sized tuft of elegant sea green, heart-shaped leaves. The stems branch freely from about half their height to the tips, and these laterals produce a succession of flowers from about mid-summer to autumn. While the whole plant is a cool emerald, the pendulous, tubular flowers are a subtle blend of shell pink and azure, thus making a most tasteful combination of delicate colour which is extremely taking. *M. sibirica* often produces self-sown seedlings about the parent plant.

GLOXINIAS, THEIR CULTURE & PROPAGATION

IS there any other flower capable of giving such gorgeous glowing colour radiance, in return for a moderate expenditure of care, as the Gloxinia? I doubt it. The Begonia is a close competitor, but here we miss the wonderful violet blue and spotted flowers that the Gloxinia provides and—to my mind—the two plants never enter into competition. They are separate and distinct. Both gorgeous, both eminently desirable, both quite indispensable. But there is a point at which similitude comes in, for both—as we know them to-day—are practically man-made plants, with a long story of patient fertilisation, cross-fertilisation, and re-crossing. As the Begonia has evolved from such lowly beginnings as *B. Pearcei* and *B. boliviensis*, so the Gloxinia has been achieved from *Sinningia speciosa*, inter-married with various other species, until the perfected plant is before us to-day, with its handsome leaves, giant flowers, ideal habit and exceedingly wide colour range.

The original kind, *S. speciosa*, was introduced into this country in 1815, a small flower, violet in colour and drooping downwards, so that one had to place the finger beneath the bloom and turn it right side upwards before one could look down into the small throat. What a miracle has since been worked! No wonder that the present race has ceased to bend its neck stalk! No wonder that the flowers raise their heads high and so disclose all the marvellous beauty of creamy throat and wondrous speckling of colour! No wonder they look one straight in the face, displaying the perfection of evenly ruled margin surrounding deep intense velvety colour. Great blooms, 3 ins. or 4 ins. across, in violet, purple, mauve, pink, red, scarlet, crimson, white of unblemished purity, white with mauve edge, mauve with white edge. Rule out pure blue and yellow and there is no limitation. A great story of progress, truly! The small drooping flowers gave place first to the semi-erect type and these, finally, to the absolutely erect flowered type with a rosette of leaves and tuft of ten to twenty flowers open at one time.

As one looks at a large house filled with Gloxinias one cannot help but wonder: "What are the latent possibilities of other seemingly insignificant flowers that surround us?"

This, however, is no time for dreaming. We have the grown plants, the gorgeous colourings, the perfection of flower and foliage. The days are lengthening and the season has come to sow the seeds. Before we pass to these, however, let one point be made quite clear. The Gloxinia loves heat and moisture and, for early flowers and early

seed sowing, these are essential; but—and it is a capital BUT, please, Mr. Printer—this does not mean that the Gloxinia is the prerogative of the wealthy. Grow your early flowers by all means, if you can, but remember that superb results are easily attained for July and August in cooler houses by starting tubers in March and April or

A TYPICAL MODERN GLOXINIA.

The illustration is by kind permission of Messrs. Blackmore and Langdon.

sowing seeds then for succeeding years. Every seed sown is a fiddle, for it contains we know not what; so that as large a number as possible should be grown on to the flowering size. And here one comes to one of the great merits of the plant, for the number of plants that one wishes to discard at flowering is surprisingly small. Poor types, to such a high state of perfection has a good strain been brought, are non-existent.

The seed is minute and those who make the mistake of distributing it too thickly will find that they have sown two kinds together—the Gloxinia seeds and the seeds of endless trouble—when pricking off time comes. Clean and well drained pans should be prepared by filling them to within half an inch of the rim with a compost prepared as follows. Take two parts of fibrous loam and add to these half a part each of peat, leaf-mould and sharp, coarse gritty silver sand, turning the whole several times until they are thoroughly mixed together. The coarser part of this should be put over the drainage and the top half inch in the pans should be finely sifted. Press firm, water lightly and stand aside for an hour or two to drain thoroughly. Scatter the seed on the surface and without covering in any way with soil, place a

pane of glass over the top, together with a sheet of brown paper, and stand in a temperature of 65° to 70°. Here the usual routine work must be followed until the young plants have made their appearance. Do not let the sun shine upon them, do not let the soil become dry; do not let the moisture that condenses on the glass remain there; reverse the glass and so dispel it again into the atmosphere. Presently, wee specks of green will appear here and there on the surface of the soil. Little specks, so small that at first one has to look twice to make sure that the eyes do not deceive. Then the brown paper must be removed to permit light (but not sun) to reach the seedlings, though the glass should be retained because of its assistance in maintaining the necessary humid atmosphere. The specks of green make rapid progress and one soon has tangible results for former care, with—oh! joyous sight—visions of "single pots" ahead; an array of rapidly growing little plants, neatly "staged" side by side and ever demanding more and more spacing out. I think that this gay glad springtime when all is hope and progress, with numberless pots filled with seedlings for which he is ever seeking further "standing room," is one of the happiest seasons in all the gardener's year.

But I anticipate, for the important work of pricking-off has first to be performed. Do not let the seedlings become crowded in the pans. If sowing has been too thickly done, it is best to lift the small plants on the point of a sharpened stick and transfer them to other pans prepared in a similar way. If not, wait until the leaves are half an inch long before transferring to separate pots. As the spring days lengthen and the sun gains power, do not overlook the inevitable fluctuation in temperature that is bound to occur, but, keep it as even as possible. Air is desirable, but must be given cautiously, remembering our starting point of heat and moisture. If the latter is abundant, a rise in the temperature to 85° or even 90° will not prove injurious; but, if the air be dry, very high temperatures spell ruination.

By early May the small pots will have become full of roots, the large, velvety leaves will be well developed and bending down over the edge of the pots and a "shift" becomes imperative. Five-inch sized pots meet the case for the first year and, in these, the Gloxinias will "prove" themselves and shew their quality before the middle of August. One must water, ventilate and care for them with unremitting attention all the while, taking care never to spill water over the foliage or to permit a draught to pass across the plants. Here, I think, we may leave the young plants, full of promise that will not be disappointed, and return again to the early days of the year, when, in addition to the seedlings, there are last year's tubers awaiting attention. These have been stored since autumn, when the last of the leaves died down as water was gradually reduced in response to the plant's evident desire to rest after its efforts. Storage has probably been effected by lying the pots on their sides in a dry place where the temperature ranged about 50°. They must now be taken out of their pots and have all the old soil shaken away preparatory to starting them again into growth. My own pet method of doing this last is to sort the tubers into sizes and arrange them in shallow wooden seed trays filled with a mixture of peat and fibrous loam. The trays stand in a propagating case right over the hot-water pipes, so that they will enjoy a uniform temperature of 70° to 80°, with a rise of 5° by day. Where batches are to be started in succession, care should be taken that those which, last year, were flowered first are used for the earliest blooms this year, so that

each may have its due season of rest. Successional batches may follow in February and March and these will start readily in a temperature of 65° to 75° by night, with a rise of a few degrees by day, so that readers will appreciate that the *Gloxinia* is a very "elastic" plant, very willing to adapt itself to the best that can be provided.

As soon as they have well "broken," the tubers should be lifted from the boxes, with as much soil as possible clinging to the roots, and then be placed in single pots. The size of the pot varies with the age of the tuber, double the diameter of the tuber being about right. Use a compost of equal parts of fibrous loam, peat and leaf-mould, well decayed cow manure and enough coarse silver sand to make its presence seen through the whole heap as it is turned about with the spade. Pot firmly without making the soil too hard and press down more firmly round the rim so that the tuber is set on the top of a slight mound, as this prevents water lodging near the crown when watering is done. Shade from bright sunlight, but grow the plants near the glass so that they will be dwarf and stocky. In about eight weeks larger pots will be necessary, using a similar compost to the above, but adding a little cow manure and bone meal. It is desirable to keep the plants a little closer for a few days after potting, then to admit air as usual, taking care that this is not in such quantities as to dry the atmosphere and that there is plenty of well diffused light. When buds begin to appear from the centre, liquid manure may be given twice a week, taking care to keep this off the leaves.

When the first flowers open, discontinue feeding and remove the plants to a lower temperature, so that the blooms may last as long as possible. Care should be taken during summer, if the days are cool and cloudy, to have a little fire to warm the pipes at night so that the air is kept light and dry. If this is not done, light coloured flowers may suffer by tiny specks of cold condensation falling upon them, which results in their becoming peppered with small brown spots.

Few pests trouble the *Gloxinia* grower if normal conditions are maintained, but if the atmosphere is allowed to become too dry, thrips are certain to prove troublesome. For these and the unwelcome greenfly, light and repeated fumigation are the only remedy; one cannot spray and syringe the foliage as is done with other plants.

Flowering completed, a very important stage in the plant's life is reached, for upon their treatment during the succeeding weeks depends the whole of their future well-being. More air must be admitted, also fuller light so that the large leaves gradually begin to turn yellow. Reduce the supply of water, not suddenly, but little by little, almost imperceptibly; the aim is not to hasten maturity, but to supply just enough to enable the leaves to complete their functions and then drive back every ounce of energy they contain into the tuber itself for the following year. When this stage has been reached and the last of the leaves has fallen naturally, turn the pots on their sides and store in the soil in a temperature of 50°. This should not be done in too dry a place; below the stage, where drip cannot fall upon the soil, is excellent though one must be sure that wood lice are not present, for I have found that these are responsible for considerable damage by tunnelling among and eating the tubers during the dormant period.

We have dealt with seeds and starting tubers, we have carried the plants through a complete season of growth, spoken of the pests that are liable to attack them and put them to bed for the resting period. Now comes the question of propagating any specially good kind that may appear—true to type. Seed will not do; cross pollination comes in and with it the inevitable variation, but leaf cuttings taken off about midsummer solve the

problem fully and satisfactorily. Mature leaves are essential and these should be taken off with the leaf-stalk attached. Where but a single tuber is required from a leaf, this may be inserted, just as it is, to the base of the leaf blade, but where each leaf has to produce several new tubers, the mid rib should be nicked here and there and either pegged or weighted into contact with the soil.

The pot which is to contain the cuttings should be filled in the ordinary way and surfaced with half an inch of sand. Place the pots in a temperature of 70°, keep just damp and, in course of time, a small swelling will form at each cut, later developing into a small, fleshy tuber. From this roots will push and eventually leaves, when the young plant is well upon its way. H. W. CAW.

NOTES OF THE WEEK

THERE is a tendency for all but the most scientific of us to attach over-much importance to our own experiences. This does not apply alone to gardening matters, but it does apply to them in a marked degree. We see an effect and grope for the cause. Our ultimate deduction may be right or wrong. Even if it be right we are apt to generalise without the necessary material on which to found a broad judgment. *Pecavi!* Because, in his experience, seedling Heaths never sprang up in ordinary sweet garden loam, though they would appear in myriads in pockets of specially prepared material, the Editor hazarded the suggestion that something, perhaps a vegetable growth, in the humus was necessary, as with Orchids, to make germination effective. Along comes a valued correspondent and squashes the idea! at any rate as regards the humus being necessary. Few of us have the time or the facilities to test our theories exhaustively. The most we can do is to submit them for the consideration of others. This is where the correspondence columns of *THE GARDEN* are of value. The accumulated experience of a number of readers from widely separated districts and with various soils and climatic conditions is worthy of respect!

Birds and the Gardener.—To publish any reference to methods of destroying superfluous bird life is always to bring down on the Editor a shoal of protests from bird-lovers, usually with extracts from the writings of Professor Somebody-or-Another, setting forth the good work that birds do for the gardener and, very possibly, citing the melancholy example of France, where birds were systematically exterminated. The comparison does not, of course, hold water. The writer of the article on "Trapping Vermin," which has elicited

a budget of protesting letters, would, we are sure, be one of the last to depreciate the good that birds do in the garden when in reasonable numbers. The majority of species, however, become a plague if too numerous, which, under the more or less artificial conditions now obtaining, they are apt to do and there seems no valid reason why Nature's sure but, seemingly, cruel reduction in the first hard winter should not be anticipated when the excess warrants interference. Jays and hawfinches when in excessive numbers make of no avail the gardener's efforts to reap where he has sown and the immense flocks of starlings and rooks in some districts not only do a distressing amount of harm themselves, but, by exhausting the insect food, drive to evil ways the blackbirds and thrushes. This is not to deny the good that rooks and starlings do when in moderate numbers, but to plead for their reduction when the flocks become too large. The same story may be told, with variations, as regards chaffinches and the various tits. It is to be feared that the "case" in favour of these latter is improved by special pleading. Even scientific gentlemen have been known to admire a shapely ankle! and the tits are certainly entertaining little fellows; so, for that matter, is the bullfinch!

The Ramondias. It is a commonplace of catalogues that these beautiful flowers need a cliff-face with a north aspect if they are to flourish outdoors in our climate. The almost perpendicular cliff to ensure the water draining from the heart is, indeed, essential, but it is not sufficiently realised that they are, in nature, woodland plants. Even in the Pyrenean forests, where they grow wild in large matted patches, they only seem really happy when on the north side of the rock which forms their home. They love a soil rich in humus

A GOOD PLANT OF RAMONDIA PYRENAICA.

CORRESPONDENCE

GREAT TITMICE AND PEAS.

MAY I be allowed the honour of being one of those "kindly souls" who would remonstrate with the contributor to *THE GARDEN* for January 6 upon his practice of "accounting for a good many tits" in the interest of his crop of Peas? Personally, I would forego the taste of green Peas for ever rather than eat them at the cost of breaking the backs of such exquisite creatures as oxeyes. I wonder whether Mr. Wood, after a successful working of his traps, has ever held in his hand the dead body of a great titmouse, and looking upon the pitiful little heap of feathers, really felt contented with his handiwork. If so, will he read the following extract from the report on this species by Mr. Robert Newstead, F.R.S., which appeared in the Supplement to the Journal of the Board of Agriculture for December, 1908, and then perhaps he will cease, even at the cost of a few pods of Peas, to rob his neighbours of these useful and delightful garden guests?

"In June, 1908, I watched a pair of Great Titmice (*Parus major*) which had a brood of 8 young, 90 per cent. of the food brought in to the young consisted of the larvæ of Geometrid moths, which were collected chiefly from the damson, apple and oak trees in the immediate neighbourhood of the nest. Those collected from the fruit trees were chiefly those of the winter moth (*C. brumata*) and those from the oak the Mottled Umber Moth (*H. defoliaria*). Usually one caterpillar was brought in to the young on each occasion, and often four visits were made in the course of five minutes. If we take the average number of visits at the rate of 24 per hour for 16 hours, representing one working day, this gives us a total of 384 visits per day. And if 20 days are occupied in rearing the young, this gives us a grand total of 7,680 visits to the nest during this period, so that the single pair of birds would be responsible for the destruction of between 7,000 and 8,000 insects, chiefly caterpillars."—R. HUDSON.

THE SCOTCH MARIGOLD.

THE old name of *Calendula officinalis* (see page 662, December 30, last), was the Pot Marigold, because the chef was wont to use the orange rays to give flavour and colour to soups and other dishes. The name Scotch Marigold may have been due to the assiduity with which the northern seedsmen grew, selected and improved it during its period of comparative neglect in the south. For some years past it has been growing in favour, with marked improvement in the size of the flowers. Our garden being overrun with small though beautiful varieties, I introduced a large one last season and, like C. T., I was impressed with its beauty and durability in the cut state. I also found that the young blooms were the most durable, because they had not completed their growth. Another feature of this Marigold is the earliness with which self-sown plants come into bloom, and the length of time during which they remain in flower. I long ago noted the profusion of blossom on the railway banks in the south-east of London, where they had escaped from gardens and kept up a display long after flowers in the garden were getting scarce. Plenty of these Marigolds can be seen flowering in Lincolnshire at the present time.—J. F.

A RECORD AURATUM LILY?

IS the following description of *Lilium auratum* a record or unusual? From one bulb planted in a pot and grown last summer in a greenhouse there were four stems bearing seventy-eight blooms, all out at the same time and a magnificent

sight, as the accompanying photograph suggests. —"SUBSCRIBER," *East Grinstead*.

[Without expressing any opinion as to the flowering of this bulb being a record, we have not

A MAGNIFICENT PLANT OF LILIUM AURATUM.

the slightest hesitation in describing it as *exceedingly* unusual, otherwise *Lilium auratum* would be even more popular than it is!—ED.]

THE CHATHAM ISLAND LILY.

SURELY the writer of the very interesting article on "The Borage Order" in this week's issue has never seen the Chatham Island Lily (*Myosotidium nobile*) in all its glory! Or is it a case of "sour grapes"? It is true that the plant is only happy in the mildest districts, as indeed are many other beautiful plants, but that does not affect its value where it does thrive. To describe "the giant forget-me-not flowers" as "blue and white," is hardly correct, for they are of a wonderfully deep intense blue with a velvety sheen, and so far as I recollect they do not shew white anywhere, even in the eye. The flowers are borne in a dense head 2 ins. to 3 ins. across, each corolla being over $\frac{1}{2}$ in. in diameter. The great glossy foliage of a healthy plant is most handsome, more resembling one of the large-leaved *Megaseas* than any of the *Borage* tribe, and forms an admirable foil to the noble flower heads. *Myosotidium* is a short-lived plant (in England, at any rate), and must be raised periodically from seed. Fortunately, seed ripens and germinates well and the young plants make good growth when transplanted to a partially shaded position in rich deep well drained

soil. At one time they were supposed to require a bed of pure sea sand, but this is not essential; where, however, sea sand is readily available it mixes with advantage be mixed with the soil of the border.

Myosotidium nobile is an extremely rare plant in nature (probably also a very ancient one, being confined to a few spots in the remote Chatham

Islands, which are famous also for being the home of the Tuatara lizard, most ancient of living reptiles. Like so many New Zealand plants (the "Lily" has been almost exterminated since the introduction of domestic animals, for it lacks the coarse hairs on the foliage and stem which in most of the *Boraginaceæ* act as a deterrent to browsing animals.

There are, indeed, few plants more worthy of trial in the gardens of south-western England and Ireland, as well as the mild west coast of Scotland. It enjoys a moist atmosphere and plenty of water at the roots in hot weather, but, of course, the drainage must be perfect.—N. G. HADDEN.

PLANTS FOR SWITZERLAND.

THERE must be some sad misunderstanding as to facilities for exporting plants from England to Switzerland. For many months I have had great difficulty in getting plants from England. Some of my friends (and some nurserymen, too!), said they could not send me plants because the Post Office asked

them for a permit from our (Swiss) Government. I wrote to the Government at Berne asking for an explanation, and *here is the answer*: "There is no prohibition as to importing plants, except as regards Roses and certain fruit trees. Other living plants do not fall under the Restriction Act and may be freely imported into Switzerland." This is the reply of the Government department concerned. Please publish this so that every nurseryman in England may know the facts and may deal firmly with your Post Office!—HENRY CORREYON.

PERENNIALS FROM SEED.

THERE are one or two points in the interesting article under the above heading in *THE GARDEN* for December 23, last, to which I should like to refer. In the first place the writer says that self-sown seedling Heaths "never spring up" in soil that is "without peat or leaf-mould," *i.e.*, fungus-carrying material. Our experience here is that we can always rely upon self-sown seedlings of *Erica vagans*, *cinerea* and *vulgaris* appearing in the raw, freshly-exposed soil of our heath bank, soil that is nothing more than poor, gritty shale. Even when this is thrown out from a considerable depth *Erica* seedlings will come up and survive where there is not too much direct sun heat. As to the Moonlight Broom, the same article

mentions this variety as one to be raised "freely from seed." Are we to understand that this very choice form can be relied upon to come true, and if so, why does it remain comparatively so expensive? I am assuming that the form referred to as *Cytisus sulphureus* is synonymous with *C. scoparius pallidus*.

Then we are told that beautiful hybrid, *Cytisus praecox* usually reverts when produced from seed. This is doubtless what one might expect, but we have grown this variety in quantity here for over ten years and have never yet seen a single seed on any of the plants, though they are laden with blossom every season. What is the explanation?—A. T. JOHNSON, N. Wales.

Truly it is unsafe to argue from the particular to the general, but the statement that seedling Heaths *never* spring up in soil devoid of considerable humus was founded on considerable personal experience. The Moonlight Broom, *Cytisus scoparius sulphureus*—the official name for the plant usually known in gardens as *C. s. pallidus*—has, in the Editor's experience, always come true from seed, but the plant from which several batches were raised was itself a stray seedling on a bank adjacent to a rubbish heap and some distance away from other Brooms. It is a little surprising to hear of the failure of *C. praecox* to seed, though it is anything but a free seeder. Seeds of it, however,

are not seldom offered by firms who specialise in perennials from seed.—ED.

THE WINTER SWEET.

NO one who knows the Winter Sweet will grudge the praise bestowed upon it by the writer of the note on page 6, January 6. I have never noticed any uncertainty, however, in the date of flowering. Here it always seems to give a few flowers in November, which gradually lead up to a full display about the end of December, and its delicious, spicy fragrance then, on a damp mild evening, is something worth remembering. There seem to be two distinct varieties, and we have both here. One has a much larger flower and never fails to carry a liberal crop, while the other, with identical treatment, gives only a few straggling blooms which are later as well as smaller. Formerly we had both on the same wall and side by side, and the inferiority of this was so marked that eventually

it came to an inglorious end in the garden fire and the other extended to fill the space. I enclose a photograph of part of this taken at Christmas. I have never known the plant to bear seed here. It is a great pity the inferior one should ever be propagated, as it can never be anything but a disappointment to the buyer.—H. C. W., *Lurgfield*.

TRAPPING VERMIN.

WITH reference to notes on "Trapping Vermin," signed H. C. Wood, in January 6 issue of THE GARDEN, I agree in deploring the action of those who, in the interests of sport, are trying to exterminate the raptorial birds and small carnivora, and would also condemn the thoughtless activity of our rude forefathers who, in the supposed interests of the human race, succeeded in killing off the large carnivora.

These, if "left to do the work for which they seem to have been created," might have made a meal of the gardener who can only manage to grow sufficient Peas and small caterpillars for his own table, and has nothing but traps for his active friend the tomtit. JOHN WATSON.

"TRAPPING VERMIN!" (THE GARDEN, Jan. 6, page 11) including, under that ugly word, tits and bullfinches! Sparrows I excuse mention of, providing, of course, it should be made clear that house sparrows are meant. The writer asks that "kindly souls should consider well the ways of nature to learn the truth about the matter." There are some kindly souls who consider very well the "ways of nature," and know the almost incalculable amount of good small birds do. No hawk, owl, stoat or weasel, however valuable in other directions, would kill the grubs, caterpillars and tiny insects which, left unobscured, would

THE WINTER SWEET, CHIMONANTHUS FRAGRANS.

prevent our having fruit or vegetables at all. Even the house sparrow does good in nesting time, feeding its young on insects. May I recommend an interesting book for perusal by all interested in Nature—"The Story of the Fields," by Fabre; it is charmingly written and contains much information.—(Mrs.) H. C. FORD, *Yealand Conyers*.

CHRYSANTHEMUM TOKIO.

I AM much obliged to Mr. Harman Payne for what he states about the Chrysanthemum Tokio. The flowers I so admired at the Monte Carlo and Nice shows had the bright colour *outside*, that is, on the back of the petals, so he will understand why I never dreamt of connecting these splendid and brightly coloured exhibition blooms with the thin and rather pale-coloured blooms I now remember to have seen in London some fifteen years ago.

Flowers grown in this clear southern light and open air are so much brighter in colour than under glass that the flowers I so praised may possibly be Tokio; but if so, it must, I think, have been treated with some special manure that has given it such a clear rose colour. In the dwarf specimen plants there were some petals in the centre that had opened and shewed a much paler colour inside, so the colour is on the *back* of the petal. Mr. Harman Payne and I may not always agree as to our standard of beauty, but I think the shaggy little single Japanese dwarf Chrysanthemums would strike him as a variant to the extremely stiff and, in my judgment, ugly dwarfs of the type of Baronne de Vindes that offend my eye exceedingly. I am sorry to say I have not seen the Paris shows. November is more attractive on these shores than even a Chrysanthemum show! EDWARD H. WOODALL, *Nice*.

"SUNSHINE IN MID-WINTER,"
CHIMONANTHUS FRAGRANS ON A WALL.

THE AFTER-CARE OF FRUIT TREES

BY now most of the new trees have been planted in the garden. I am often asked the best plan to adopt with regard to their treatment subsequent to planting. It is an all-important question, for a young tree can quite easily be made or marred at this stage.

Pruning we will take last, and apart from this the treatment consists in maintaining the correct amount of moisture and nourishment. I ought to mention that I am taking the case of quite a young tree throughout, say, from a maiden to a four year standard; and not so much large, more mature trees which are often moved and replanted. It is difficult to start young, newly planted trees growing well and producing much wood the first year, and thus every effort must be made to conserve moisture and to feed for growth. If it is convenient to water them, of course this is excellent in moderation and should certainly be done. If, however, this is impracticable, frequent hoeings around the roots should be given, thus helping, to great extent, to conserve the moisture. When I was a boy I could never make out why hoeing ever kept in the moisture, it seemed to me that it would tend to allow the water to evaporate more quickly, and even older men are rather puzzled now. The fact is that there are a very large number of minute tubes in settled ground leading upwards to the surface from the moisture-holding earth below. The moisture is drawn up these tubes by capillary attraction and, on reaching the top, of course evaporates. It is easy to understand, then, that by hoeing these tubes are broken and, as it were, stopped up, thus preventing the moisture from escaping. This information seems rarely to be given in text books, but is useful to know. Hoeing is extremely beneficial for conserving the moisture.

One of the best plans, however, is, about April, to mulch each tree with good straw dung which, besides keeping the roots damp, will feed them and enable the trees to make much better growth.

The question of pruning newly planted trees is a very debatable one, and opinions differ, but the plan I give below is the generally accepted one. The first aim at this age is to promote growth and a good shape, but the question is whether to prune soon after planting or to wait until the following autumn.

Now, where the trees were planted very early in the autumn as soon as the leaves started falling, they have had a chance to form new root fibres immediately and, in the following year, will have the power to form strong and reasonably long new wood. In this case it is advisable to prune, say, in the February following planting, and provided the land is not too poor in plant food (nitrogenous especially) they will make quite considerable numbers of good shoots the following summer. This only applies to early planted trees, as it should not be done with trees planted in late winter or spring.

The policy with these is to defer the pruning for one year, as they will have made no appreciable move the summer following planting, and their root system will only just be making headway. If pruned, they will only make weak wood averaging not more than jins, or jins, in length.

Now, during the winter, a year after their first pruning, the new shoots require to be thinned out—bearing in mind the best shape for the tree in after years and the positions for the branches. Cut out weak side shoots useless for making

branches, leaving only the leading growths at the ends. These leaders should be cut back to half their original length so as to encourage, in the following summer, strong new wood suitable for retention in the tree to form more branches.

A year later the above plan should again be followed, cutting back to two buds those shoots which cross or rub against one another, and also those which are not wanted to form the shape of the tree. This time cut back the leaders to two-thirds and the next year the tree will be taking on a really good shape, easy to pick and to spray. If worked on the Paradise stock it should also be

forming a few fruit-buds. Of course, in later years the *modus operandi* will consist of thinning the branches and pruning according to variety and various other considerations which will be found in any good text book on the subject.

If suitable varieties are chosen at the outset, good pruning and waging unremitting war on insects by grease-banding and spraying will make the garden orchard a source of continual delight. Not only will the result be satisfactory from a pecuniary standpoint, but there will also be much sheer pleasure gained in tending and admiring trees worthy of any garden.

—SIR J. H. L.

WINTER FRUIT SPRAYING

Spraying is of such real value and importance that it should be one of the routine winter tasks in every garden, instead of in the comparatively few as at present. The health and strength of the trees are improved and, consequently, much better fruits are given.

IT is freely said by the commercial fruit growers of the country that one of the principal reasons why woolly aphids and numerous other pests are so prevalent and so persistent is that the owners and managers of private gardens, large and small, do not adopt adequate steps to destroy these pests; in fact, that the majority of private gardeners, large and small again, do not take any steps at all.

This is a very serious indictment and, at the risk of treading on the toes of a strictly limited few readers of THE GARDEN, one is forced to believe that there is substantial justification for it. There are hundreds of gardens within whose gates a spraying machine has never been seen, and there are hundreds of others which may boast the possession of a good machine that has not been, and is not now, used. Appliances are at hand or can be purchased at reasonable prices and excellent washes are advertised regularly in these pages.

Why, then, is not spraying or washing or dressing, or whatever anyone may choose to call it, a regular winter operation? Can it be asserted substantially that the fruit trees in private gardens are not heirs to the enemies which attack them when they are grown in commercial gardens? Can it be asserted that the enemies bred in private gardens do not migrate thence to other pastures as they do from one commercial garden to another? Is the operation so difficult of accomplishment or so objectionable in application that the private gardener cannot or will not undertake it? Has not the private gardener reliable knowledge of what to apply and when to apply it? Or, is it that private gardens are so inadequately staffed that it is impossible to find the time requisite, not merely to do the work, but to do it well, as it must be done if it is to justify itself? One concludes that the cause of neglect lies chiefly in the last-named difficult position and in the fact that there are still private gardeners, just as there are still commercial growers, who have no belief in outdoor spraying, whether it is directed against the enemies of vegetables or fruits. Enough of one aspect of the matter. Let us turn to the work itself or to such of it as should have attention during the period when the trees are at rest.

Winter washing has for its objects the removal of lichens and mosses on the bark of bole and branches, of enemy eggs where this is possible, and of enemy larvae lurking in congenial nooks and crannies in the rough bark and in the forks. At the present time there are three standard solutions for this purpose, the oldest of which is lime wash, the next a caustic wash and the junior lime-sulphur—and the last named, having been invested with wondrously varied powers, is the

most popular. Which is the best under all conditions it is quite impossible to say.

As an occasional dressing lime has no superior, but it cannot be employed advantageously season after season. It is a splendid cleanser, and any eggs which can be added it will account for, and the foliage of the trees will be finer in texture and richer in colour in the season following. Application should be made through an easy jet and not through a spraying nozzle, as no matter how carefully the straining has been done blockages, causing irritation and waste of time, are sure to occur. The quantity used should be abundant to the point of extravagance completely to coat every inch of bark and to fill every nook, cranny and fork, leaving plenty over to go on the ground, where it will do an equal amount of good, though in a different manner, as all gardeners know. The one serious objection to it is that men simply abhor handling it and will make any excuse to evade the task. However, that is a little matter which must be adjusted by employer and employed on the merits of each case.

Springing from first to last, we will now speak of the immensely popular and convenient lime-sulphur. No one can seriously question the usefulness of this wash provided that a compound of the highest grade is bought and that it is efficiently applied, but it must not be anticipated that it will equal either lime or a caustic wash in cleansing the worst encrusted trees of lichens and mosses. A perfect solution will be richly gorgeous in hue and quite clear, and when it is reduced by the addition of water it will be characterised by a perfume which is very much not that of my lady's boudoir. Whether it is required in big or little quantities, it should be purchased and not compounded at home, because the manufactured article is vastly superior to the home product. It should be bought under a guarantee of 1.3 specific gravity. If the appliances are clean, it can be used through any nozzle, and it should not be stinted, though there is no justification for wastefulness. It is of outstanding value for regular application to keep clean trees in a proper state of cleanness, and it can be used at practically any time, with the proviso that there must come reduction in strength with young shoots on the plants, and that particular care is taken in its use for American gooseberry mildew, in the suppression of which it has been proved to be of the utmost value.

Now to the caustic wash, which is probably the most effectual destructor of lichens and mosses of all winter dressings. It can be procured in several forms according to the main object of application, but, in the simple state, it consists

of 1 lb. of caustic soda, 98 per cent., dissolved in 10 gallons of water, and its greatest value is reached when it is applied fairly hot. It was urged some years ago that the addition of crude commercial potash was a substantial advantage, but as a matter of fact it does not improve it in the slightest degree, and may therefore be ignored. When it is scrubbed hot on to rough bark worked vigorously into nooks, crannies and forks it will destroy lichens and mosses almost instantly, and neither egg nor larva can withstand it. In those parts of the trees where it is impossible to scrub it must be applied through a spraying machine, and there can be no doubt as to the value of fineness of division, since it is that which adheres and not that which runs down that is beneficial. Therefore

use the finest available nozzle and drive until the solution comes forth in a dense mist, as none will then be lost. It is not the nicest stuff in the world to handle, as there is no question as to its powers of burning. Old clothes, old boots and old gloves (good rubber ones are better still) and a wideawake hat ought to be worn, and the operator of the sprayer should be scrupulously careful to stand with his back to the wind to avoid the irritation of burning drops on the face and the taste of even minute quantities in the mouth. There is one point in connexion with it that may well be impressed, and that is to use it during the dormant period only, since it will burn anything that shows the slightest signs of active life.

W. H. LODGE.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Brussels Sprouts.—For an early supply an autumn sowing should have been made, but if this was not done seeds may now be sown in boxes and the seedlings raised in a cool pit or greenhouse. To secure first quality Sprouts a long period of growth is necessary, and to this end a sowing should be made in the open ground as soon as the soil is suitable. Two reliable varieties are Exhibition and Scrimger's Giant.

Lettuce.—Seed may be sown in boxes of light soil or in frames, selecting a cabbage variety such as Tom Thumb.

Spinach.—A sowing of this desirable vegetable should be made in a sheltered situation. To keep up a supply another sowing must be made a fortnight hence, and so on for the next few months. To secure fresh succulent leaves, the seedlings must be thinned early and the soil kept free of weeds.

Leeks.—The main crop of Leeks may be sown during the next week or two, selecting a piece of ground that recently has received a liberal dressing of decayed manure. Leeks enjoy a rich soil and ample room for development, so the seeds should be sown thinly in wide drills 1 ft. apart.

Carrots.—If a cold frame is available it should be utilised for Carrots, choosing a quick maturing variety, such as Scarlet Horn. Old potting soil is excellent for placing in the frames. After the soil has been made fairly firm and level, sow the seed thinly over the surface, raking it in with an iron rake. Keep the soil just moist and admit air whenever the weather is mild. A partly spent hot-bed is also suitable for an early supply of Carrots and Radishes.

The Flower Garden.

Antirrhinums.—During the last few years these delightful plants have become exceedingly popular, and it is not surprising when we know how excellent they are for bedding purposes. The best effect, no doubt, is produced by beds of a single colour, rather than a mixed display. For general bedding the intermediate varieties are to be recommended. Seed may now be sown in boxes of light soil placed in a warm greenhouse. When the seeds have germinated, remove the boxes to a cooler structure, keeping the seedlings fairly near the roof glass. Avoid over watering or they may damp off. When the young plants are large enough to handle prick them off in boxes or frames a few inches apart and admit air whenever the weather is suitable. If frames are chosen, arrange them on a hard bottom, fill up with a few inches of light soil and when the pricking off is completed keep the lights closed for a few days until the plants are re-established. Snapdragons should be grown as cool as possible to promote a sturdy, short-jointed growth.

Propagation. Continue to propagate such plants as Coleus, Heliotrope, Marguerites and Salvias, and pot off Pelargoniums ready for tilling the flower beds in May.

Fruit Under Glass.

Strawberries. A batch of plants should now be introduced to a cool house, and after a week or two the temperature should be increased to 55°. Gentle forcing, especially in the early stages, must be practised or the crowns will fail to produce a

satisfactory crop. On bright days a light syringing overhead with tepid water will be beneficial, but this must be discontinued while the plants are in bloom. Over watering must be avoided, but the roots ought never to suffer from lack of moisture. When the flowers are open lightly touch them with a rabbit's tail or large camel-hair brush, keep the atmosphere on the dry side and ventilate the house each day when the elements are favourable. Directly it can be ascertained which are the best fruits, the inferior ones should be removed, and the plants then fed with liquid manure or Le Fruitier.

Tomatoes.—Seeds may be sown in pots of light soil and if they are piced in a temperature of 65° germination will soon be apparent. When the seedlings are through the soil, keep them within reasonable distance of the roof glass, and pot them off singly in a mixture of loam and leaf-mould directly they are large enough. Never permit the roots to become starved.

The Hardy Fruit Garden.

Neglected Orchards.—For some reason orchard trees are sadly neglected, they are seldom pruned or sprayed, and the fruit is often inferior in quality. The present is a good time to look over the trees, cutting out all dead wood, thinning the growths especially in the centre, and shortening any branches that may be interfering with neighbouring trees. The object is to allow sunshine and air to get among the trees at all seasons of the year.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),

Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Parsnips.—The remaining roots should be lifted and pitted row to permit of the ground being dug or trenched, and so be in readiness for spring cropping.

Early Peas.—It is too soon to recommend the sowing of even early Peas generally; still, those who have the advantage of a rather light soil and a south border with a wall behind may chance an early sowing now if the condition of the soil permits. It will only be necessary to fork over a breadth of about 18 ins. along the lines where the Peas are to be sown. Do not sow too deeply and partially fill up the drills with some old potting soil and a sprinkling of wood-ashes. Laxton's Superb, The Pilot and William Hurst are suitable varieties for this sowing. Before sowing damp the seeds and roll them in dry red lead so as to ward off the attacks of mice or rats.

Jerusalem Artichokes. As the growth of these commences early, the remainder of the crop should now be lifted and stored in sand or light soil in a cool cellar or out of doors.

The Hardy Fruit Garden.

Supports for Fruit Nets. Crops of bush fruits can be picked much more comfortably when a framework a little higher than the bushes is provided for supporting the nets than when the nets are allowed to rest on the bushes. Where such framework is already in existence it should be examined and repaired if necessary. Those who intend to introduce this system should have the structure erected before the rush of spring work comes on.

The Flower Garden.

Lily of the Valley.—Although one would not suspect it, Lily of the Valley is a gross feeder, and requires liberal cultivation to provide really good spikes of bloom. Autumn is the best time for forming fresh plantations, but the operation can be successfully performed in spring just as the plants are beginning to move. Those who contemplate spring planting should have the bed or beds prepared as soon as possible. Trench or double dig the soil, and if it is at all stiff, add sand or light soil and incorporate a good quantity of farmyard manure with the soil as the work proceeds. Established plantations should receive a liberal mulching of farmyard manure.

Top-Dressing Bulbs.—Established beds of Dog's-Tooth Violets, Scillas, Fritillarias and other small bulbous plants should be top-dressed with fresh fibrous loam or old potting soil mixed with half-decayed leaves.

Auriculas.—Beds of Auriculas, Polyanthes and Primroses are all benefited by an annual top-dressing as recommended for small bulbs, as they incline to get leggy if left to themselves. The application of a suitable top-dressing results in the emission of fresh roots from the necks of the plants, which means their reinvigoration.

Gladioli.—The foliage of these will now thoroughly be ripened, so the corms should be freed of the foliage and all loose coating and stored in a dry, cool place ready for starting indoors or planting in the open.

Dahlias.—Sufficient tubers should, during the next fortnight, be brought into a vinery that has been started or other warm structure to furnish cuttings to be rooted later on. Dahlias are deservedly popular at present.

Fruit Under Glass.

The Early Vinery.—Vines which were started early will require disbudding. The best time to carry out the operation is just as the buds burst, rubbing all out except the strongest one on each spur. The night temperature for Hamburgs at this stage should be about 55°. Muscats require a rather higher temperature. Ventilate slightly whenever there is bright sunshine, partly to avoid sudden fluctuations of temperature and also to induce a firm, sturdy growth from the start.

Tomatoes.—Plants resulting from seed sown early in December should now be ready to pot off. Use zin. pots, and a good preventive against damping is to place the plantlets near the edge of the pots instead of in the centre. Another sowing may now be made to provide plants to be grown in frames or other cool structures. For this purpose it is best to employ varieties that produce good trusses of rather undersized fruits. Stirling Castle and Lister's Prolific are typical examples.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Salvia Heerii.—Most of the greenhouse Salvias flower during the autumn, but *S. Heerii* has the advantage of flowering early in the New Year, thus frequently escaping the fogs that so often spoil the autumn-flowering species in the neighbourhood of London. *S. Heerii* may be propagated during March or April, and the resultant plants may be planted out during the summer, lifting and potting them up in the autumn and wintering them in a cool greenhouse.

Cyclamen.—Young plants that were raised from seed last August and pricked off in pans or boxes for the winter, should—if not already done—be potted in thumb pots. At this stage they enjoy a light, rich compost, to which some old mortar rubble should be added. For some time yet they should be grown in an intermediate temperature, standing the plants on a shelf well up to the roof glass.

Chrysanthemums.—Cuttings of the general run of decorative varieties should be secured without delay. They may be rooted in a slightly heated case, but this is not really necessary; in fact, I prefer to root them under perfectly cool conditions, in a case in a cool house, or in shallow cold frames. When cold frames are employed, it is a good plan to use shallow boxes, placing a sprinkling of fine ashes at the bottom. The cutting pots should be stood in the boxes and then covered with panes of glass. This is an excellent method of propagating many plants when the ordinary facilities of proper propagating cases are not available.

You can't Dig a Garden—

with good intentions and a hairpin. There has to be some honest spade-work.

You can do your digging and weeding with anybody, but you have your little weakness like the rest of 'em! You like to *look* as though you'd done it. A little perspiration, and good honest dirt thick up to the elbow!

Well, and why not? Just walk about a little where the neighbours can see you, and then—KIT.

KIT soap will clear every atom of dirt, grease, oil, paint or tar out of your hand, and will do it nearly twice as quickly as anything else. It is a nice "spready" sort of soap, so you need only a little. The tin is blue and orange (the handy shape and the handy size), and the lid comes off just when you want it.

Keep a tin in the house for cleaning after "odd jobs."

Price 6d. per Tin.

HOW TO PRUNE ROSES & FRUIT TREES.

A most helpful booklet by OWEN THOMAS, V.M.H. Sent post free on receipt of 11d. "COUNTRY LIFE" Offices, 20, Tavistock Street, Covent Garden, W.C.2.

Hibbertia dentata is a very charming evergreen climber for the cool greenhouse. It has a long flowering period during the winter and spring is easily propagated by means of cuttings, and usually ripens plenty of good seeds.

Hibbertia Readii is a very different species, making a small compact plant suitable for pot culture, and in its season produces its small yellow flowers in wonderful profusion. Being a native of Australia it is, of course, well suited for the cool greenhouse or conservatory. It is propagated by means of cuttings of half-ripened wood, using small twiggy growths about 2 ins. in length. The cuttings should be inserted in pots of sandy peat and stood under bell glasses in a cool pit.

Lopezia miniata is a very charming spring-flowering plant for a cool house, producing its small rosy-red flowers very freely. It is easily propagated from cuttings and it pinched several times it makes compact bushy plants and may be grown outdoors during the summer months. In Devon and Cornwall it is more or less hardy.

Roses in Pots.—In most private gardens Roses in pots are not grown very successfully. This is not due to absence of skill in cultivation, but, generally, to lack of proper accommodation. It is usually difficult to grow Roses really well unless a house is devoted to them. Where such facilities do not exist, the dwarf Polyantha varieties can often successfully be grown, and they are useful as they last in flower for a long time in a cool greenhouse. Pot Roses usually do best if they are established for a season in pots, but the dwarf Polyantha varieties can be lifted from the open during October, potted up and stood in the open. Where this was done a batch of plants may now be pruned and placed in a cool house. A temperature of 55° is high enough to commence with, but as the plants start into growth this may be increased to 60° and 65° during the day. The house or section of the house where they stand should be carefully ventilated, avoiding draughts, which are very apt to cause mildew. As a preventive or cure they should be sprayed with liver of sulphur, using 1 oz. to a gallon of water; it 2 oz. of soft soap is added to every three gallons of water it renders the mixture more adhesive. When the plants are in full growth they enjoy frequent applications of diluted liquid manure.

Perpetual-flowering Carnations should be propagated, as good cuttings can be secured, and in the ordinary way are best rooted in pots of light sandy soil, standing the pots in a case in a cool house. Under cool conditions they take a little longer to root, but the resultant plants are generally more sturdy. Plants rooted during the autumn should be potted on as they require it. They succeed best in good medium loam, with little or no leaf soil, but sufficient clean coarse sand, or old mortar rubble added to keep the whole porous. Lime in some form is essential for Carnations, and the plants should be firmly potted. Plants coming on for flower should be disbudded and kept neatly staked and tied. J. CORRIE.

Royal Botanic Gardens, Kew.

Bluets.—The *Houstonias* or Bluets are remarkably pretty little alpines, which, when in bloom are full of charm with their myriads of neat little flowers which quite smother the small leaves and adorn a plant only 3 ins. or 4 ins. high. A comparatively small number exist and of these there are only some two or three species in commerce and the possession of one will probably be enough for most rock gardens. Not but what all are beautiful, but there is a considerable resemblance between them, and those who have *Houstonia coccinea* need not long for another. It is certainly one of the best. It has been well described as a "little gem," for it is truly gem-like when in bloom. It forms a small plant with delicate-looking tiny leaves and many little flowers of a delightful delicate shade of greyish blue. There is also a white variety, which is scarce, but is not a bit more beautiful than the blue one if, indeed, as attractive. The other species occasionally offered are *H. purpurea* and *H. serpyllifolia*. The cultivation of the *Houstonias* requires some consideration. They like a light, well drained soil, but must not be allowed to become too dry at the roots. Given plenty of water in dry weather they can stand a good deal of sun, but a somewhat shady

place is desirable and a flat ledge, or terrace, suits them best. It is desirable to give an occasional soaking of pure water now and again in dry weather in spring and summer, and this attention is well repaid by the greater health of the plants. A very desirable point to consider is that as to whether the plants should be allowed to form seeds or not. In garden practice it is very much better to cut on the blooms as soon as they are past, preferably when all but a very few have become withered.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

HOW TO ARRANGE AND PLANT A HERBACEOUS BORDER (M. S.).—The soil should be deeply dug and the subsoil loosened with a garden fork. The plants must be put in far enough apart to allow of ample space for each clump to develop in later on without being overcrowded. The naturally tall-growing kinds and varieties should be planted at the back, the medium near the centre and the dwarfier ones at the front, but too much formality should be avoided. The following are suitable kinds to plant. The number of each should be obtained according to the space to be filled. *Delphiniums*, *Aconites*, *Echinops*, blue; *Anemone japonica*, *Chrysanthemum leucanthemum*, white; *Anemone japonica rubra*, *Asters*, rose; *Lycynis chalcidanea*, *Tritoma*, *Phlox*, crimson; *Tritoma*, *Helianthus*, *Rudbeckia*, yellow; *Asters*, *Erigeron*, *Delphinium*, purple. These for back part of border. *Campanula*, *Gentiana montana*, *Scabiosa caucasica*, blue; *Achillea*, *Campanula*, *Lilies*, white; *Peonies*, *Pyrothrum*, *Phlox*, pink; *Gaillardia*, *Lycynis*, *Benedicta sanguinea*, crimson; *Coropsis*, *Doronicum*, *Gum*, *Monarda*, yellow; *Iris*, *Pyrothrum*, purple. These are for the middle of the border. *Anemone appennina*, *Gentiana*, *Viola*, blue; *Pinks*, *Phlox*, *Achillea rupestris*, *Viola*, white; *Lycynis viscaria*, *Pinks*, *Aubrietia Leichtlinii*, rose; *Carnations*, *Pinks*, crimson or scarlet; *Aureolia*, *Primrose*, *Viola*, *Alyssum*, yellow or orange; *Aubrietia*, *Viola*, *Gentiana*, blue or purple. These are for the front part of the border. As the soil is of a retentive nature, it is probable that some of the bulbs may perish, but not all, as sand was placed round them.

TREATMENT OF LILIUM GIGANTEUM (N. L. R. Loughton).—The bulb should be potted in a 7 in. pot at once. Use good fibrous loam, a small quantity of peat and sand. Leave the crown of the bulb uncovered, place the pot in a cold frame, but admit air freely night and day except in frosty weather. The object is to induce a slow strong growth of stem. In April plant the Lily in the open border, burying the stem about 3 ins. with a light compost, which should also surround the roots 6 ins. thick. The hole should be made in a naturally dry border in an open position sheltered from north-east and south-west winds. Remove the border soil to a depth of 18 ins. and 2 ft. in width, fill up with the lumpy, fibrous loam and a fair quantity of well rotted manure. Water carefully and protect the bulb with dry litter or bracken if it is left in the border during the winter. Use any off-sets for propagation.

FUCHSIA CODRINGTONI (S. P. R. Carditt). There is no mention of the name of the above *Fuchsia* in the gardening dictionaries or books. We have searched the "Index Kewensis" and its five supplements and the name is not recorded. About two years ago Messrs. Isaac House and Son exhibited some flowering plants of it at a meeting of the Royal Horticultural Society. The small size of the leaves and flowers and upright habit of the plants showed that they were related to *Fuchsia microphylla* and *F. thymifolia*, but nearer to the former, and differing by being a little larger in all their parts. The two *Fuchsias* just named come from Mexico. The only chance of its being a species would be if the plant has been introduced and not named by a botanist. Our opinion is that it is a garden hybrid with *F. microphylla*, perhaps, as one of its parents.

THE GREENHOUSE.

FREESIAS UNSATISFACTORY (C. Bath). Two of the *Freesias cornus* appear to be quite healthy but have failed to produce roots. The third has been damaged by some biting insect some time ago. *Freesias* sometimes fail to grow, but the cause of this trouble is unknown. It is probably due to some stage of the ripening process having been improperly passed. Sometimes, however, such corns will grow after a rest of a year. In our correspondent's case the shoot is beginning to appear without roots, and this usually means that the temperature of early growth has not been correct.

NAME OF FRUIT.—H. D. Suffolk.—Apple Melon.

MAKE THAT GARDEN OF YOURS

as profitable and as lovely as the one you have so often admired. Ensure Vegetables enough to share and to spare all the year round, and of much more delicious quality. Flowers, a perennially gay display, rivaling in charm the garden of your dreams. Your joy over one perfect feature has not subsided before you find that another and yet another have reached the same high plane.

Send a post card to-day for our absolutely **FREE** 160-page illustrated **GUIDE TO GARDEN WISDOM AND GUARANTEED GARDEN SEEDS**. Ensures your Garden doing its very best. Every packet of Seeds, too, purchased thence **MUST GROW** for you, and please you, or you will get it replaced freely. No obligation of any sort, but address us personally to-day:

TOOGOOD & SONS, Ltd.

Seedsman to H.M. The King, and Growers of
"Better Crops" Seeds only.

SOUTHAMPTON.

Notes from Maidstone.

SINGLE ROSES.

The interesting note of these charming flowers in January 6th issue reminded us that we can offer a good selection, and should specially recommend the following varieties:

*Irish Elegance,
Irish Glory,
Princess Mary,
Sheila Wilson,
Isobel,
Glow-worm and
Simplicity.*

These are all 1/6 each,
except Cupid, 2/6, and
Mermaid, 2/6.

SUTTON'S ANTIRRHINUMS

"The Bedding
Plant of to-day."

The "GARDENERS' CHRONICLE," writing in Aug. 1922, says—

"ANNUALS AT READING.—The Antirrhinum, which for garden purposes may be regarded as an annual, is increasing in favour each season, and there are few gardens in which this beautiful and simply-grown plant may not be found. Reading might almost be said to be the home of the present-day Antirrhinum, for Messrs. Sutton and Sons have long paid especial attention to this valuable flower."

Continuing with reference to
SUTTON'S "NEW BEDDING" VARIETIES
the same paper says:—

"The raising of a new strain possessing all the merits of the Tom Thumb type without its failings has long been the goal of florists, and at last it is near attainment, for there is evidence that before long a Dwarf Intermediate strain will be available. It is now an open secret that the strain has been fixed—indeed, this is abundantly evident to the visitor, who can see long rows of dwarf plants each exactly like the other so far as size and form are concerned, and they embrace practically all the delightful colours and tones of the older established types."

We now have pleasure in offering this "New Bedding" strain in the following nine colours:

White, Yellow, Apricot, Pale Pink, Bright Pink, Buff Pink, Cherry Pink, Fire King, Orange Red.

Each per packet, 1/6

[JANUARY 27, 1923.]

WHITE FLOWERS FOR THE BORDER

HERE and there throughout England one may find, instead of the more usual rose, rock, bamboo or wild gardens, what the owner calls a white garden; that is, one composed entirely of white-flowered plants with, perhaps, suitable evergreens. To us this does not seem a desirable arrangement, for surely the main function of white flowers in the border is to provide relief for those of warm colouring. Even so, plants with flowers of dead white colouring should be used with discretion, or they are likely to drown the colour effects they are intended to relieve.

How often does one see a rock garden bank looking in spring-time anything but attractive owing to a great preponderance of *Arabis* and *Perennial Candytuft* (*Iberis sempervirens*), both plants which, unless checked, outgrow and outseed their neighbours! Again, what a multitude of herbaceous borders display overwhelming masses of *Chrysanthemum maximum*! The cold masses, insufficiently relieved by colour, are depressing in the extreme. After viewing them one can well understand why the Chinese chose white as a mourning colour! This must not be taken to convey utter condemnation of the three plants mentioned, all useful enough in their way and the last named, at least in a good form, very beautiful. They should, however, be used with discretion.

Theoretically, white is a subtle combination of all the colours of the spectrum and, as such, incapable of shades or tones such as we are used to in the primary colours. In practice, hardly two white-flowered species or varieties are the same colour. There are whites tinged with blue, whites tinged with red, whites tinged yellow, to say nothing of those shaded with two colourings in combination. Thus there are whites faintly empurpled and others toned with green; only in flowers an untinged white is hard to find if, indeed, it exist.

Perhaps we have a paved garden—paved with self-faced York

stone of a brownish grey. We shall use plants with crimson or purple flowers (diluted purples as well as strong ones!), those with soft yellow tones and those with grey foliage. Two classes of white flowers will suit this company—those faintly tinged with purple—*Campanula carpatica alba* and *C. lactiflora alba*, for instance, and those with a yellow tinge which we variously call creamy white or lemon white, according to the strength of the tint. Such, for example, are cream Hollyhocks, *Verbascum Miss Willmott*, *Chrysanthemum maximum* *The Speaker*, *Lupinus arboreus albus*, most

white Bearded Irises and white Delphiniums (but not *Moerheimi*), white Foxgloves, white Pinks, *Clematis recta*, *Spiraea Aruncus* and all the white-flowered forms of the Meadow-Sweet type, the Plume Poppy (*Bocconia cordata*) some of the white forms of *Anemone japonica* and *Campanula alliariaefolia*.

The flowers of most white Lilies are tinged with yellow, and the golden anthers appear to some extent to "gild" the interior and enhance the effect. The white garden Lily is still, of course, the *Madonna Lily*, *Lilium candidum*,

though for selected positions the glorious white form of *L. speciosum*, called *Kratzeri*, is even more beautiful. Here a green tinge predominates. The hardy alpine form of the Philippine white trumpet Lily, *L. philippinense formosanum*, comparatively speaking a dwarf, also bids fair to be valuable for the border. Tinged with red and green without and yellow within, it should be admirable for the paved garden. Though actually almost dead white in colour, the golden stamens also give a hint of yellow to the *St. Bruno's Lilies* (*Anthericum*), which, when once established, are sufficiently charming to be worthy of a site specially selected to shew them to advantage.

Among the hardy Bearded Irises a pure white is most nearly represented by *Kashmir White*, which, having blood of the sacred *Iris kashmiriana*, is not quite so accommodating a garden plant as are most of the Bearded sorts. *I. florentina* can only be described as whitish, yet for that reason it is invaluable for some groupings where anything approaching pure white would quite eclipse the subtle mauve, rose or bronze shades with which it was associated. Where the soil is naturally cool, *Iris levigata alba* will, with ordinary cultivation, flourish in the border. It is very beautiful; so are some of its descendants listed as varieties of *Iris Kampferi*. Some of these are practically pure white, but those faintly tinged with blue or mauve are equally valuable

MADONNA LILIES.

Most of them are the apparently simple and of the attractive complex Daisy flower. The roughness is better expressed in a tree-rose of *Claytonia virginica*, but there is a very pleasing dwarf Daisy which might be used more extensively than it is. This is *Anthemis Cupanana* with white golden-eyed blossoms which are sufficiently effective to justify its place and grey-green foliage which is a joy when the plant is out of flower.

Such things as *Gypsophila paniculata*, particularly the single form, and *Gallienia tritohata*, though white-flowered (or in the case of the *Gallienia* partly so), provide an effect of lightness rather than of whiteness in the border; the same may be said of *Tunica Saxifraga*, whether white or pink.

The Campanula family is singularly valuable for the number of white-flowered plants it provides. In addition to those already mentioned there are admirable white forms of *Campanula persicifolia*, single, semi-double or double to suit all tastes; besides the useful white variety of *C. latifolia* and the elegant *C. bononiensis alba*. *Campanula glomerata alba* is rather uncommon in gardens, but more desirable than the typical purplish form. The Chimney Bell-flower, *C. pyramidalis*, is in cultivation as often white as mauve. It is perfectly hardy in well-drained, rather hungry and decidedly limy soils, but is not a long-lived plant. A batch should be raised from seeds each year, for it is among the sturdiest and most useful of border plants.

The white forms of *Lupinus polyphyllus* are apt to be "dirty" in colour, but some of the new hybrids with arboreus have creamy flowers faintly but pleasingly tinted with purple or rose. The beautiful white Everlasting Pea known as White Pearl can be usefully employed in the herbaceous border, but it must not be trained too stily.

For early summer there is nothing more beautiful than that splendid white form of the Rocky Mountain Columbine called *Aquilegia cornuta* Munstead White, while the pure white double form of the Common Columbine *Aquilegia vulgaris* is also quaintly beautiful.

The Spiræas and Astilbes seem to affect white or creamy tones, and for cool soils they are invaluable. On light land, however, they are useless except in specially selected shady places. *Astilbe rivularis* and *A. r. major*, the latter especially valuable because of its height, are excellent. That fine white Goat's Rue, *Galega officinalis* Niobe, is invaluable for sun or shade, while for nearer the front of the border there is the form called *alba compacta*.

The Cimicifugas (Black Snakeroots) have foliage much like that of the Spiræas, but their towering white spikes do not need more than the usual amount of moisture to bring them to perfection. *C. racemosa* is summer-flowering; *C. simplex* is an early autumn bloomer. The former is the taller, reaching 4ft. or more in good soil. Two of the Asphodels are also effective because of their spiry effect. The white Asphodel, *Asphodelus albus*, is a fairly accommodating plant, but *Asphodelus luteus* is useful only for sheltered corners with protection from the east.

There are many admirable white Pæonies, both single and double, and some with very pale sulphur-colored blossoms, equally beautiful. Pontstemon, White Newbury Gem is well known, but some of the pale florists' hybrids are useful. There is not a pure white one, of course. A useful white dwarf petunia is *stoezi virginiana*, while in addition there are *Moræ*, *Sedums*, *Veronica* and *Viola*.

Yet, on reflection, there is still room for good white herbaceous plants, for we still have to have white and cream Daisies to add variety to the summer border!

USEFUL AMONG HERBACEOUS PLANTS—HYDRANGÆA PANICULATA GRANDIFLORA.

THE INVALUABLE PHLOX.

WATER AND BOG GARDENING

I.—Mainly Constructional.

NOT in the swiftly running stream where the water ripples and dances along with gay and babbling voice, bearing a thousand messages upon a thousand tongues, but in the quiet backwater and bays where—without stagnation—tranquillity reigns is the home of the water plants. There Dame Nature has placed *her* water garden, and there on the placid surface rest countless blossoms of wondrous beauty. In the water garden every beauty is duplicated in the mirror-like surface of the pool. Here one can see again the azure of the sky above, watch the clouds and the birds as they pass overhead and note the long-drawn shadows of the trees, pictured almost as clearly as when one looks directly at them.

Then—when we turn our attentions from the water itself to the surrounding ground—an equally varied and unfamiliar range of plants presents itself to view: Marsh Marigold, Sweet Flag, Flowering Rush, Water Arum, etc., with their feet in the water, thronging the margin; while, in the bog and on the banks that are a little further removed, Gunnera, Podophyllum, Cyperus, Spiræa, Loosestrife, Primulas, Globe Flowers, etc., combine in forming a picture of unparalleled beauty.

Is it any wonder that, with so great a prodigality of beauty spread before us, the desire arises to transfer it to the garden? Is it any wonder that "water" gardens are becoming increasingly popular? That even the wee rock pool has become quite a feature of the rock garden? Assuredly not. The surprise would be if it were not so. Of course, it is but seldom that one is so blessed as to possess a natural piece of water, "ready made" as it were and only waiting for the importation of plants, but there are many gardens in which it is possible to plan and plant a water garden that shall be a joy to its owner.

There are several types of water garden. One may have the formal circular or rectangular pool, stone or cement curbed, in which a few of the delightful Water Lilies, creations of M. Latour Marliac, shine like jewels and around which, in summer, great tubs of African Lily or Hydrangea are placed. One may confine one's attention to the wee rock pool, but little more than an overgrown bird bath, in which the tiniest aquatics—such as *Azolla caroliniana*—float, kings of their little world. Yet again—and I am not sure that this is not the best of all—one may have an informal "garden" 10, 12, 20 yds. square, in which a varied collection of aquatics are living, surrounded on the margin by bog plants that, as the banks rise further and further from the water's edge, give place to plants of moisture-loving habit. Even if one has none of these, it is still possible to enjoy the smaller-growing Water Lilies—*pygmea*, etc.—by means of barrels cut in half and either stood upon, or sunk into, the ground, so that they are upon a level with it. In all cases one thing is necessary: means must be taken to ensure that the tank, pond or lake is water-tight and will not sink below a certain level. Even in cases where natural water exists this point ought to be kept in view when planting. One must plant so that, even in times of drought, the plants do not stand high and dry above the water which is essential to their life.

To return to our artificially made pond. In selecting a site it should not be lost sight of that

water finds its level, so that, if there is any variation in the height of the ground, one should choose the lower position. A place as open and sunny as possible is very desirable, for sun-heat warms the water and thus conduces to growing conditions. Roughly mark out the outlines, whether a formal circle or irregular "natural" form, and then excavate the soil to the required depth. This should vary, as by this means a wider variety of plants can be grown; but the greatest depth should bear relation to the size of the pond. Thus, in a very small pond, the greatest depth perhaps will be 18 ins.; whereas in one 15 ft. square it might well be 3½ ft. deep at the centre, shelving upwards on all sides to the margin, where it will be about 18 ins. A variety of means is used to make the

with a metal bung attached to a chain so that it can be drawn out either from the margin or a boat.

If a small rock pool or dripping well is proposed in connexion with the rock garden, this should be as informal as possible in character. There is an art in disguising art that is never more valuable than where dealing with the water garden. Artificiality must not obtrude its presence or everything is ruined. In the rock garden the margin is a great asset in this direction, and by judicious planning and planting can be made to conceal all "man's work" that it is desired to screen, while at the same time appearing part of the rock garden itself.

Still another possibility of water gardening remains that has not been mentioned at all—the

ADMIRABLY PLANNED AND PLANTED.

pond water-tight, depending partly upon the nature of the soil below it and the kind of pond or tank that it is to be. On a heavy soil the work is comparatively simple, for one has but to work the clay by beating and kneading until it is thoroughly tenacious, and then line out the excavation to a thickness of gins. or 1 ft. This lining is rammed and beaten all over as finely and as quickly as possible, so that it forms a uniform "basin" without any cracks in it and, as soon as finished, water should be admitted so as to prevent any shrinkage or cracks from forming in the clay. In the case of small or formal ponds, digging out is done in the same way, and then the interior is lined with concrete surfaced with cement, which should be well tested before planting to make sure that it is water-tight. In the case of ponds that are small, cement is the most satisfactory; but where a larger area is proposed, clay puddling and ramming is far less costly. In all cases provision must be made for draining, to facilitate necessary cleaning and attention to the plants; the best way being to connect the lowest point of the pond with a length of pipe that can be stoppered

brick-built tank. This is more difficult to place well, perhaps, than any of those—except the circular or rectangular pool—that have previously been mentioned. Obviously, it is artificial, and therefore consorts best with artificial surroundings. It is the companion of the flight of steps, the stone flagged path and, possibly, the sundial. Again, one digs out the soil to the required depth, but—this time—instead of puddling with clay or lining with concrete, bricks are used. The thickness of the wall must vary, of course, with the size of the tank—that is a question for the mason or bricklayer—and, when done, the inside should be lined out with a coating of cement. Bricks are porous and cannot of themselves retain water. The edge of the tank should be laid down with a curb, formed of the bricks themselves laid either flat or edgewise.

The water supply in the majority of cases will have to be an artificial one, and it should be remembered that—while this should never be allowed to become foul—it is desirable to change the water as seldom as may be consistent with healthy growth. Water drawn from the mains is terribly cold from the plant's point of view,

and the aim should be to change it as seldom as strict cleanliness demands. Fish and water snails should not be overlooked in this connexion, for both are valuable allies. If one is lucky enough to be able to connect one's water garden with a stream, spring or river, one has ideal conditions, for all that has to be done is to construct a small inlet and another small outlet to provide a steady, quietly flowing stream that cannot stagnate.

Always, in the case of the natural or informal water garden, attention should be paid to the bank immediately surrounding the margin. Let its outline undulate. Water never leaves hard margins, nor does it wriggle uselessly, while a gentle slope down to the edge is far better than a sudden quick drop. One cannot approach the margin with pleasure for nearer examination of the flowers where such a drop exists, and it is usually easy to slope away the bank a little so that this difficulty is overcome. Do not entirely

surround the margin with plants, leave some "open country" here and there so that the planting falls into groupings, allowing a vista of the more distant parts of the garden beyond.

So much, then, for the general principles of making and planning. One must choose the method best fitted to the garden with which one has to deal, using all possible artistry to conceal the artificial handiwork, unless, indeed, it is to be frankly artificial.

H. W. CANNING-WRIGHT

THE GENUS COTONEASTER

Continued from page 39.

THERE are several forms of, or species closely allied to *C. microphylla*, the best known being *C. congesta* (syn. *C. microphylla* var. *glacialis*) and *C. thymifolia*. *C. congesta* is distinguished by its shorter branches and dense growth. *C. thymifolia* has distinctly narrow leaves. It is best to propagate these distinct forms by cuttings or layers as they do not come true. At least, that is our experience at Kew, though this may be due to cross pollination as all three are growing in close proximity.

C. MULTIFLORA.—As a specimen bush or small tree this Chinese species is easily the best flowering Cotoneaster for the lawn or border. Here again there is much to be said in favour of vegetative propagation for a form received at Kew from Paris is of outstanding merit compared with others of more recent introduction from China. The Paris specimen has a single central stem with a round head some 10ft. high and 12ft. through, of gracefully arching branches. The wealth of white blossoms are produced in May. *C. multiflora* (*C. reflexa* of some nurseries) is deciduous.

C. PANXOSA.—This is a tall evergreen shrub of tree habit up to 12ft. or more in height. Though

individually small, the white blossoms are freely produced in corymbs of twelve to twenty flowers at the end of June and early July. From *C. Francheti* it differs in being a taller shrub, and has leaves of a duller green hue, which are also not quite so large. Following the quantities of white blossoms are usually an abundant crop of red fruits in autumn. As an evergreen screen

in the wide shrubbery border or as an informal hedge, this Cotoneaster possesses considerable merit. It was first introduced from Yunnan to Paris by the Abbé Delavay in 1885.

C. ROTUNDIFOLIA.—A sub-evergreen species usually, this well known fruiting Cotoneaster grows 6ft. to 8ft. high. Retaining the rich red fruits until February or March it is perhaps the best of all the species for large lawn beds and

CRIMSON FRUITS OF COTONEASTER SIMONSI.

masses in the pleasure grounds. It has distinct rigidly arranged branches, with dark glossy green leaves and is one of the largest fruited ($\frac{1}{10}$ in. diameter) Cotoneasters. *C. rotundifolia* is a Himalayan shrub first introduced in 1825.

C. SALICIFOLIA.—This is an evergreen species of comparatively recent introduction from China. The young plants are growing freely and are distinctly graceful and attractive in habit. In flower it is one of the most showy species, with corymbs of white blossoms, followed by quantities of small, bright red fruits. The variety *floccosa*, introduced from Western China by Mr. Wilson in 1908, has grey or silky white under surface of the leaf. The variety *rugosa*, as the name suggests, has rather larger and coarser leaves than the type. This also was first introduced by Mr. Wilson from China. He collected seeds in W. Hupeh in 1907. This group of Cotoneasters is said to grow up to 10ft. or 12ft. high.

C. SIMONSI.—In mild winters this Cotoneaster retains many of its leaves until Christmas, though one would scarcely be correct in calling it a sub-evergreen. It grows up to 8ft. or 10ft. high and is an excellent shrub for massing and invariably berries freely, these being scarlet, $\frac{1}{10}$ in. to $\frac{1}{8}$ in. in diameter. It is a native of the Khasia Mountains. Several sprays of this Cotoneaster were staged at a recent meeting of the Royal Horticultural Society under the name of *C. "Simmondsii"*, obviously a wrong spelling as the plant is named in compliment to a Mr. Simons who collected many herbarium specimens in the Khasia Mountains.

C. TURBINATA.—This is a vigorous evergreen Cotoneaster which came to us from China *via* France in 1910. Already we have a beautiful lawn specimen 10ft. high. The leaves are dark

THE EVERGREEN COTONEASTER SALICIFOLIA RUGOSA.

dull green, the under surface being clothed with grey-white felt. The feature of this species is the flowering season, late July, when the white

blossoms are freely borne in corymbs 1 in. to 2 ins. or 2½ ins. across. The fruits are dark red, about ½ in. long.

A. O.

THE NICOTIANAS

THE common very fragrant "Tobacco Plant," *Nicotiana glauca* ("affinis" of gardens), has by its beauty and perfume occupied such a stronghold in our gardens that we are very much disposed to pass over all other kinds, save perhaps the red Tobacco, *N. Sanderiana*. So far as floral display is concerned, there is but little room for question that these two are the very best; but neglect of other species is regrettable, for there is much that is beautiful, much that is interesting, and much that is unusual left outside.

Some years ago an examination of the list of names in a seed catalogue stimulated my curiosity, and I experimented rather extensively among the unknown, so that at the end of May I found myself with a number of boxes of healthy seedlings ready to plant out. Then came the question, Should they be used in groups, disposed among the beds and borders, or should they occupy all by themselves a small piece of border that had not been planned? Decision was reached; the latter course was favoured, and so up grew my little Tobacco border, representing over half a dozen kinds and ranging in height from 2 ft. to 6 ft. I would that words could paint it more realistically. That readers could see the growing plants in the evening light of a summer's day and inhale the powerful perfume as it combined with a little foreign-grown "weed" as it slowly charred to white ash burned in the pipe. That border was an entire success, and never failed to call forth exclamations of "I had no idea there were so many kinds."

A few words must be said upon the method of raising from seed, for, to obtain the best results, particular points must be noted. It is a mistake to sow too early. It is easy to get Tobacco plants too forward, and if they once begin to spindle up into a flower-stem before they are planted out, they will never give first-class results. Seedlings do not grow rapidly in the earliest stage; but, once a certain period of development has been passed, this is changed and small plants speedily become larger. From the second to the third week in March is a good time to sow, while a temperature averaging 55° is about right, and this will give sturdy little plants in sufficient time to permit of their spending a good while in cold frames to harden off before planting out. Sow the seed thinly in shallow pans, being careful not to overcrowd, for if an excess of water should at any time be given, crowded seedlings go down by "damping off" like wildfire. Use light soil, cover sparingly with this, keep just moist and in an even temperature, and there will soon be a plentiful crop of seedlings waiting to be pricked off. Boxes will do quite well for the pricking off, though it pays to give each plant a small pot to itself. This latter was the plan I followed with my border, but more space is required and, of course, the labour of watering is increased. Keep watch upon the condition of the plants all the while, but particularly as the spring advances, so that they are timed (by careful regulation of temperature, air, etc.) to become close, sturdy little rosettes of foliage without a hint of flower-stem pushing by late May.

Just here I would most strongly advocate another most important point in culture—early planting. The Tobacco is, we know, half-hardy, but far harder than is generally supposed, and

with a warm, sheltered position in which to plant and thorough hardening off and in not too bleak a garden, it may safely be trusted in the open ground any time after the middle of May has passed. Indeed, I have proved over and over again that it is those earliest planted which do best. Frost, of course, will kill the plants if at all severe, but bar that (and it is generally easy to provide temporary protection if requisite), early planting always scores. Rich, well manured soil is appreciated, and although heavy shade is detrimental, partial shade is not harmful.

Now, having procured our stock of young plants—which, by the way, look singularly alike at this stage—let us take a glimpse into the future.

THE FRAGRANT WHITE TOBACCO, *NICOTIANA ALATA*.

Grouped at the back in bold masses are *N. glauca*, a species with curiously blue-green foliage and pink flowers; *N. Tabacum virginicum*, the Common Tobacco, 4 ft. high, with rosy purple flowers; and *N. sylvestris*, a most uncommon species of similar height. The latter makes immense leaves and a stout central stem, bearing at the apex a large number of long, drooping, tubular flowers that remain open all day. This is splendidly effective and, if one has a large bed upon the lawn which it is desired to fill with a very bold and imposing plant, one can scarcely do better. In front of these are *N. alata*—lavishly used—filling the air with an almost overpowering volume of fragrance and at evening a sight worth walking far to see. At the opposite end is a corresponding patch of *N. Sanderiana* in vivid carmine. At the centre of this forward grouping, and stretching well to the front, an immense foliage plant is prominent, *N. gigantea*. This is a majestic plant indeed, 4 ft. high with handsome crimson flowers.

Use the Tobacco plants how one will, as an entire small border or planted in groups in border and bed, they are always effective.

RUSSET APPLES

THESE should be more generally grown. They are, as a rule, free croppers and of fine flavour. Although the fruits are not so showy as those of many varieties very generally grown, the flavour of most of the Russets is really good. The trees bear when quite small, are fertile, and the matured fruits keep sound for a long time. The fruits of some varieties shrivel with age. They are, however, more appreciated by many lovers of Apples when this shrivelling has taken place. Personally, I much preferred some of the small Russet varieties found in old orchards and cottage gardens nearly forty years ago to some of those of more recent introduction. I well remember their great cropping and keeping qualities. The following are a few of the best russeted varieties. This is a good time to plant.

AROMATIC RUSSET.—In season December to February. Flesh firm; not a large fruit,

but of rich flavour. This is one of the oldest sorts.

BOSTON RUSSET.—In season from January to end of May. Very richly flavoured, suitable for dessert or cooking.

BROWNLEE'S RUSSET.—In season from Christmas to end of April. A dessert variety of medium size, sweet flavour and very fertile.

EGREMONT RUSSET.—In season from October to December. This is one of the most attractive of the Russets. Rich yellow with deep russet markings, crisp, highly flavoured, fertile and of good habit.

ST. EDMUND'S RUSSET.—In season from September to November. Dessert, medium size, a golden russet, free fruiting and richly flavoured.

SYKE HOUSE RUSSET.—In season from December to March. This is a small variety, but a very valuable dessert Apple.

It will be seen that these Apples cover a season from the end of September to the month of May. Usually the trees are not over-robust and will repay really good treatment. **GEORGE GARNER.**

FRUIT AND FLOWERS AT VINCENT SQUARE

THE brightness of the exhibits at Vincent Square on January 16, when the first R.H.S. meeting of the year was held, augurs well for a successful season. Frequently the early shows are "thin" and uninteresting, but on this occasion, although the hall was not filled, there were sufficient exhibits of Orchids, Carnations, spring bulbs and other flowers to make a very attractive Show.

Nor was the colour and attraction confined to the floral exhibits. There were two gold medal exhibits of Apples and Pears of most delightful and high quality; while in the collection of vegetables by Messrs. Sutton and Sons the centre of variegated Kale had considerable beauty of form and colouring. The other and less showy vegetables were also of that high quality associated with the Reading firm. The Royal Favourite Leeks, Tender and True Parsnips, Onions, Beet and Carrots were all of the best exhibition standard; while for those who prefer more uncommon vegetables there were the Vegetable Whitebait (*Stachys tuberculata*), Pink Fir and Congo Potatoes, of value for saladings, and unusually fine roots of Salsify.

While the two fruit exhibits were quite distinct in their styles, both consisted of Apples in very many dishes and a few of Pears of such great merit as fully to justify the high award they received. As ever, Messrs. G. Bunyard and Co. displayed great taste and skill in arrangement. Many of their Apples were beautifully coloured, but it was those of such rich golden colour as Norfolk Beauty, Waltham Abbey Seedling, Golden Jubilee, Golden Noble and Golden Spire that first took the eye. Then one realised by contrast the brilliance

of many other sorts, particularly Worcester Pearmain and Wealthy. The dishes of such Pears as Catillac, Josephine de Malines, Bierré Perran and Double de Guerre were of remarkable quality.

The collection set up by Mr. J. C. Allgrove seemed to rely solely upon its high quality and here the dishes of Apples—Spitzbergen, Cox's Orange Pippin, Scarlet Pearmain, Wealthy, William Crump, Seedling A, a most handsome dessert variety—and the quantity of magnificent fruits of S. T. Wright were all as near perfection as possible. The Pears included Foydale's St. Germain, Easter Beurré and Santa Claus. The last named is a high-flavoured Pear of medium size that is still in season and continues good for a longer period than the generality of Pears.

Carnations have been on view at the shows and in the shops so long and so regularly that one is inclined to take them for granted and not to appreciate the great advance that has been made of late years in their cultivation during the winter months. This is, none the less, true, and such a gorgeous vase as that of Edward Allwood in the collection of Messrs. Allwood Brothers was not possible only a few years ago. This firm also had very attractive stands of Wivelsfield Fancy, Wivelsfield Claret and Triumph. Their Allwoodii seem to be of ever-blooming character, for they were able to make quite a nice show with them.

Great as has been the advance in brightly coloured Carnations, it is ever more apparent in those of yellow colour and these were very prominent in the collection of Mr. C. Engelmann, who had

very good vases of Saltrion, Jessie Allwood, Marion Willson and Marie Sun-lune. In sending such a large collection of Carnations blooms from his gardens to this first show of the year, the President of the R.H.S. gave a valuable lead to other amateurs who, it is hoped will follow Lord Lambourne's example and share their plants and flowers in this way. Their new pink varieties, Mrs. T. Ives and Filene Low, were prominently displayed by Messrs. Stuart Low and Co., who also shewed winter-flowering Begonias, Azaleas and Mimosas. Among the last named was a plant of *Acacia Baileyana* which is fast superseding the longer leaved *A. dealbata* in the shops, and on the itinerant vendor's barrows. Besides being equally as beautiful in flower, *Acacia Baileyana* is hardier, flowers when quite small and its shorter, silvery leaves do not flag when the sprays are cut.

Other greenhouse flowers included particularly good Cyclamens by Messrs. Blackmore and Langdon, who, besides large batches of splendidly grown plants of Salmon King, Giant White and Giant Crimson, had a new variety somewhat similar to Sutton's Firefly which received an award, and the similarity was continued in the name, which is Fireball. This is apparently a larger-flowered sort than Firefly, but there seems to be a shade more blue in the colouring.

Spring flowers, even thus early in the year, were prominently displayed. Messrs. Sutton and Sons had a large collection of Hyacinths of enviable quality. These were mostly from "prepared" bulbs, which undergo a special treatment in order that really good spikes of Hyacinths may be forced into bloom by Christmas with quite reasonable

BLUE HYACINTHS IN MESSRS. SUTTON'S EXHIBIT.

THE ADMIRABLE SALMONY ROSE CAMELLIA JUPITER.

certainly. These were shewn as large baskets in all colours. The bowls of the rich yellow Tulip *Mon Trésor* contrasted well with the deep blue of *Iris reticulata*.

Besides Hyacinths Messrs. R. and G. Cuthbert, had good pots of *Freesia retracta* alba and white Christmas Roses. Many Polyanthus, double

shewn is a vivid vinous ruby-red but we have seen it at Reading when the hint of blue noticeable on this occasion was entirely absent, and while all the leaves were lightly mottled, those on one plant were as distinct as Silver-leaved Salmon. The plants were very floriferous. Award of merit to Messrs. Sutton and Sons.

"VIVID VINOUS RUBY-RED"—CYCLAMEN FIREFLY.

Daisies and the graceful little blue *Anchusa myosotidiflora* were shewn by Mr. G. W. Miller, while at the end of the hall Messrs. Chaplin Brothers of Rose fame, who have absorbed Paul's of Waltham Cross, shewed some floriferous little *Camellia* bushes. Such single sorts as the bright salmon-rose *Jupiter* and the white *Novelty* were especially delightful.

Chief among the few alpine flowers were the little patches of the dainty hardy *Cyclamens* in the exhibits of Messrs. Waterer, Sons and Crisp, and Mr. G. Reuthe, while Messrs. Wallace and Co. had a number of pans of the interesting and beautiful *Crocus* species—*C. triflorus*, *C. Imperati* and *C. Sieberi* are the names of only a few of these fascinating flowers. They also had sprays of several species of *Hamamelis* wreathed with flowers. In their rockery Messrs. W. Cutbush and Sons placed a bush of *Garrya elliptica* which bore plenty of its curious catkins, while Mr. G. G. Whitelegg had a collection of dwarf conifers eminently suitable for planting in rock gardens, as well as interesting and lifelike hand paintings of Bearded and Japanese Irises.

Mr. Percy Cane's garden design photographs are a standing, but none the less interesting, feature of the winter shows. The plans and views exhibited are continually changing. On this occasion interest was largely focussed upon a number of excellent designs for town gardens.

NEW AND RARE PLANTS.

Cyclamen persicum Firefly.—The half a dozen or so plants of this new greenhouse *Cyclamen* in a round basket made a delightful patch of vivid colouring and the novelty is all the more welcome in that the flowers possess the added charm of the true *Cyclamen* form and do not flop about as do so many of the gianthybrids. The colour as

Brasso-Cattleya British Queen.—A magnificent bloom of large size and perfect form. The sepals are of rosy mauve colouring, the large lip is of darker shade in front and it has a pale yellow centre. Award of merit to Mr. Pantia Ralli.

Cymbidium Curlew var. Feather.—This beautiful variety is considered to be the best of the Butterfly and *Alexandere* crosses. The plant bore a large spike of pure white flowers which have faint mauve lines and rich ruby-red spotting on the lip. Award of merit to Sir George Holford.

Cymbidium Doreen.—The experts were of the opinion that this is the best dark *Cymbidium* in cultivation. The tall spike bore seven large blooms of deep bronzy-purple colouring, relieved by rich golden yellow on the margins and occasionally in the body of the flowers. Award of merit to Messrs. J. and A. McBean.

NEW FRUIT.

Apple Ball's Pippin.—The award to this late dessert Apple was conditional on the sub-committee being satisfied with the tree and its qualities when they inspect it during the coming season. The fruit is of Rival shape and the green skin is occasionally flushed with red. The flesh is white and was said to be sweet and of good flavour. It is a cross between Cox's Orange and Sturmer Pippin. Award of merit to Mr. J. C. Allgrove.

FORTHCOMING EVENTS.

January 29.—British Florists' Federation Annual Meeting and Dinner to be held at the Connaught Rooms, Great Queen Street, W.C.2. Annual Meeting at 3.30 p.m. Dinner at 6.15 p.m.

January 30.—Royal Horticultural Society's Fortnightly Meeting. National Hardy Plant Society's Annual General Meeting at the R.H.S. Hall at 2 p.m.

VENTILATION: ITS USE AND ABUSE

GIVING ventilation to glasshouses is a science not easily mastered. It is difficult to teach, very difficult to learn and it is made more difficult by many unnecessary operations. A head gardener may give his young men the most minute instructions as to how to act and yet in some emergencies he may find that he, with all his experience, cannot act in the same way as he has instructed his pupils. When there is continued sunshine or continued dull weather, continued cold or continued heat, the matter is simple enough, but the unexpected so frequently happens that the most experienced may not know what to do from one minute to another. These emergencies test the skill of the cultivator and make all the difference between success and failure. Of course, everybody has failures whether he is skilled or not. The man who says he has no failures never reaches the top of the ladder. The one who would excel must be bold and run some risks, but one of the first lessons to learn is to know why we practise certain details. Some of our forefathers did wonders with the means at their command, but we must not be content to follow them blindly now that conditions are very much better. Our houses are better, especially in regard to light and heating appliances, and thanks to scientists, our knowledge of plant life and plant feeding, and the effects of light is, or ought to be, much better than that of our predecessors.

Why do we give ventilation to our glasshouses? Certainly not for the same reason as we give it to a dwelling house, excepting so far as it is done to prevent the temperature rising too high. To sustain animal life it is necessary to have a certain amount of oxygen and a minimum amount of carbon dioxide. For vegetable life the reverse of this is required. Our plants would revel in a much higher percentage of carbon dioxide than they obtain in the ordinary way. Some scientists tell us that they flourish in an atmosphere containing 2 per cent. of this gas, and our ordinary atmosphere contains less than one part in three thousand. Then what is the use of leaving ventilation all night on a house where the fruit is in full growth and the plants are not inhaling carbon dioxide, but giving it off in the act of respiration. Our predecessors had a reason for leaving a chink of air on, to allow the sulphur fumes from their flues to escape. The flues are gone, but the practice still lingers. It may suit the sluggard, but not the genuine gardener.

Early ventilation on a bright morning is very important, and the lower the night temperature of the house, the more important is this timely attention. There may have been a shade temperature of 40 degrees on the previous evening and the amount of moisture contained in the atmosphere with this temperature is very considerable. As the temperature lowers the capacity of the atmosphere for holding the moisture in suspension lessens and much of it is deposited on the leaves and fruit, which lose heat faster than the atmosphere does, and just as the sun's rays are about to reach the house this deposit is at its maximum. The ordinary cultivator follows the rule laid down by many calendar writers and waits till a certain temperature is reached before giving air, the temperature being, in his opinion, the thing of greatest importance. The skilful cultivator knows better. He would rather give ventilation a little too early than five minutes too late. The effects of tardy ventilation are plainly seen on white grapes, for these, during the

first week or ten days after the flowers commence opening, are liable to what is called rust, though it is not visible till a later stage. Black varieties may be just as badly affected, but it is not so apparent to the naked eye. A high night temperature will prevent this happening, but it will not be good for the fruit, nor for those who have to pay for the fuel. Well, if this happens to the Grapes, which shew the effects, can it be supposed that it is harmless to other plant life? In giving ventilation at any time, do not lower the temperature by giving it—always anticipate the rising.

Supposing the outdoor temperature is down to freezing point and that of your house, owing to an unexpected change in the weather during the night or early morning is down to 45°, when it ought to be 10° higher. Before the sun's rays actually reach the house the temperature will commence to rise and when they actually reach it the rise will be rapid. If a little ventilation is

given the temperature will not rise so rapidly and it should be remembered that the greater the difference between internal and external temperatures, the greater will be the velocity of exit. When there is a difference of only 15°, it will not be nearly so rapid as when there is a difference of 20°, through the same aperture.

Now, if it was only the heat which escaped the effects would not be so disastrous, but, unfortunately, it carries with it much of the moisture which makes the atmosphere genial. Therefore, if you allow the internal temperature to rise to a considerable extent before opening the ventilator, you bring about such a rapid exit that it will have a similar effect to what one would feel when emerging from a warm bath into a draughty passage, in fact, it brings about a chill, though gardeners are wont to call it by another name. If a practical and sensitive cultivator enters a house at 10 o'clock on a bright spring morning, he can generally tell

by the feel of the atmosphere whether the ventilation has been skilfully managed, for even after there has been a considerable amount of damping down, the harshness produced by tardy ventilation is evident for some hours.

I wish to impress on readers that the ill effects to which I have alluded are not often produced by a reasonably high temperature, but by a sudden change of atmospheric conditions. On a changeable windy day in March one may see young men running from one house to another altering the ventilation for every passing cloud or glimpse of sunshine. This does more harm than good. I very seldom give any ventilation to Vines which are not being forced, before April, and sometimes not till the middle of that month. A range of temperature from 45° to 90° by sun heat will seldom do any harm to Vines up to the stoning stage if ventilation is not insisted on.

WM. TAYLOR.

NOTES OF THE WEEK

THE first Fortnightly Meeting of the year at the Royal Horticultural Hall was a surprisingly good one both from the point of view of the exhibits and from that of attendance. During the afternoon the hall was, indeed, quite as full as it should ever be if visitors are really to see the exhibits. If the hall can be thus filled at this dead season of the year, it will no doubt be more overcrowded than ever during the coming summer when, to make space for more exhibits, the gangways will be narrower.

More Space?—From the beginning of March till the end of June all the shows at the Vincent Square hall will be two-day events, which is calculated to some extent to relieve the congestion. This relief, however, is very partial, for many flowers can only be seen satisfactorily upon the opening day. The trade, too, object to the two-day meetings as absorbing valuable time and increasing the expense of exhibiting without any corresponding increase of business. There is a disposition in some quarters to ignore the convenience of the trade in this, as in other matters, but it should be kept steadily in mind that without the support of the trade it would be impossible to hold these shows at all. What is really needed is more space. Although no doubt it will be possible to make shift with the present hall for another season or two, the Council has to face the fact that these shows are rapidly outgrowing the accommodation provided for them. There seems, unfortunately, no possibility of extension on the present site, though for some years there was a plot of vacant land adjoining one side of the hall. Sooner or later the question of a new building will have to be faced and the sooner it receives, at any rate, preliminary consideration the better.

Wisley Trials.—The Royal Horticultural Society has a large and still growing membership and handles each year a very considerable income, but its outgoings are also on a large scale, so that if anything worth while is to be put aside towards providing fresh and larger accommodation, it would be well to pass the various items of expenditure under review previously to a vigorous use of the pruning knife. A very considerable portion of the expenses of the Wisley Gardens must be absorbed by the annual trials of various kinds of flowers, fruits and vegetables. It appears to be the general opinion of Fellows of the Society that these trials represent little more than a clean, sheer waste of money. These trials could, at best, only decide what varieties suit the rather unsual

soil of this particular garden. Actually they are in fact quite unrepresentative, since many of the most important firms conduct trials of their own and, rightly or wrongly, refuse to support those at Wisley. We are confident that if a plebiscite of Fellows of the Society were taken the Council would be surprised at the small amount of support these trials would receive. Leaving the question of a larger hall quite aside, more money might, with advantage, be spent upon other and more interesting features at Wisley than the trials. To be perfectly frank, there is very little at Wisley at any season of the year that a Fellow would be likely to take his gardener to see. Indeed, beyond the very pleasing laboratory building, there is very little for *anyone* to see there. Certainly the gardens are far less interesting now than in the earlier war years.

At the forthcoming general meeting Fellows might do worse than to ventilate this question of the trials and the Council's policy with regard to Wisley.

The Hardy Plant Society.—We hear from the Secretary that considerable interest is being taken in the re-organisation of the Society. If really effective work is to be done a largely increased membership is imperative. There must be thousands of keen amateur gardeners whose enthusiasm is mainly directed to the culture of hardy plants. Every one should join the Society and, if possible, join it before the Annual Meeting on 30th instant. Subscriptions should be sent to the Hon. Secretary, Daetvils, Caversham Road, Reading.

An Alpine Pink.—Earlier described the subject of our picture, *Dianthus callizonus*, as "far beyond competition, incomparably the loveliest of Alpine Pinks," and few who have seen it well established will be inclined to dispute his judgment. The plant is stoloniferous and, when happy, quickly forms patches of considerable size. The flowers are bright pink in colour—pink with a touch of salmon. It is, par excellence, a plant for the limestone moraine.

THE BRILLIANT ALPINE PINK, *DIANTHUS CALLIZONUS*.

CORRESPONDENCE

STRAWBERRIES AND ASPARAGUS.

PERHAPS I should make it clear to Mr. W. H.

Lodge and other readers that my note on Strawberries was not meant to apply to commercial growers of large acreage for the fruit. For amateurs I hold to what I wrote, and Mr. Lodge seems to agree. But beyond this I cannot see why commercial growers for sale of plants should not adopt the maiden plant system. It takes little time to nip out the flower-trusses and the loss of fruit hardly matters. I cannot help demurring to Mr. Lodge's assertion that "runners of practically equal excellence and earliness can be secured from one year old plants, as has been proved time after time by skilled cultivators." My own experience of some forty-five years on different soils says "no," and I can only ask readers to try both methods and report results. The garden is small that cannot afford room for twenty-five maiden plants to give 100 runners. Squares of turf are in some respects better than pots, but firm turf is not always to hand, and pots can be more easily moved to hard ground and kept a few days in case of forced delay of planting out. As to Asparagus, I think Mr. Lodge will own, on consideration, that his comparison with Narcissus bulbs is not quite logical. If a variety of Narcissus would come true from seed (which it won't), I could get a much speedier increase and probably healthier plants by gathering the seed from a batch of plants and sowing it. As things are, the plant's nature obliges me to lift, divide and replant. Asparagus, on the other hand, comes practically true from seed, and hardly any plant dislikes disturbance more obviously. Why then, unless you are in a desperate hurry for a year, go to the considerable pains and expense of transplanting?—G. H. ENGLEHEART

THE GOLDEN SCOTS PINE.

I WAS glad to read (page 25) Mr. Clarence Elliott's appreciation of this delightful little Pine. It deserves all his praise. Oddly enough, if he got his golden Thyme from Mr. E. Charles Buxton, it was the latter who introduced me to *Pinus sylvestris aurea*, a fine specimen of which has been growing for many years in the famous Bettws-y-Coed garden. The colour of this dwarf Pine is really remarkable, especially in mid-winter, and when the needles are wet with rain they gleam like polished glass. Our specimen is exactly 30ins. high and about 24ins. through at its widest part, which is near the ground. It is a very slow grower, as Mr. Elliott says, the above plant not making 2ins. a year. It, of course, looks best with some green background. Our bantling has, besides turf for company, a common but dwarf Juniper from the Scottish hills on one side of it, while spreading about some lichened rocks over which the Pine presides is a mat of *Juniperus prostrata*.—A. T. JOHNSON, North Wales.

DECORATIVE SHRUB SPRAYS.

WHILE agreeing with Mrs. Barron (see page 23 of THE GARDEN, January 13) as to the usefulness of shrub sprays for house decoration, I am very doubtful as to their superseding flowers for this purpose. No doubt there is a certain appeal about a nicely arranged large vase of some of our choice berried shrubs, but I am afraid the great majority would vote for "the enormous and costly Chrysanthemums and Carnations," which, considering their lasting qualities, are not so very costly. Here, in Carlisle, sprays of berried shrubs are offered for sale in the flower market

every week during winter, and only a very limited quantity of these and purchasers. The past year has been one of the best on record for fruitfulness of shrubs of all kinds, and many wonderful pictures were to be seen almost everywhere of trees and shrubs literally covered with beautiful berries. One feels that it is thus that the great charm of berried shrubs is best appreciated. Not when the sprays are cut and artificially arranged in a jar or vase. — ALFRED.

THE CORDYLINE AUSTRALIS.

DURING the past summer this *Dracena* has flowered freely in many parts of the country where the conditions are mild enough to allow of its being grown. Beautiful as the large flower-spike is growing out of the massive head of yucca-like foliage, it is usually so high up on the plant that a close examination of the flower is impossible. It may not be generally known that if the flower-spike is cut and placed in water it will last for many weeks; its thousands of tiny cream-coloured flowers, sweetly scented, remain fresh for a long time. The seed in December is quite as beautiful as the flower in June. The berries are pure white, about the size of small peas; they hang on the plant until January, when they are often eaten by birds. The seed-spike in the illustration was cut just before Christmas, and proved as decorative and lasting as did the flower in June. *Cordylina australis* is probably not hardy inland. On the west coast of Scotland, however, it grows splendidly and flowers most years. Last summer we had 100 blooms all out at once. There are more berries than usual this winter. Self-sown seedlings frequently appear near the old plants.—KENNETH McDONALL OF LOGAN, Port Logan, Scotland.

THE WHITE MARTAGON LILY.

I HAVE been greatly interested by M. Henry Correvon's delightful article in THE GARDEN (page 657) on European Martagon Lilies. His descriptions of Alpine flora in their native homes

FLOWERING SPRAY OF CORDYLINE AUSTRALIS

THE CORDYLINE IN BERRY.

bring back memories of many happy days and walks in those regions (in May and early June) beginning with the glorious sight, on emerging for the first time from the St. Gothard Tunnel, of the rugged cliffs on each side of the railway covered with the horizontal plumes of Saxifrag. Cotyledon waving in the wind. I was especially interested in reading M. Correvon's description of the white Martagon Lily in natural conditions.

My first acquaintance with this Lily began nearly twenty-six years ago, when I first came to my present home. There were then very few flowers in the garden, but there were the purple-pinkish Martagon Lilies in abundance, and to my great astonishment, as I had never before seen it, the lovely white ones with their orange anthers, similar to those described by M. Correvon. They come up every year, and the white ones seem to increase in numbers. I have tried to get plants of them to give to one of my most generous gardening friends, but it is quite impossible to reach to the end of the root; they seem to go down for many feet into this fairly stiff soil. I see that Miss Jekyll, in her delightful book on "Lilies for English Gardens," describes the white Martagon as the "Greatest treasure of the Martagons, a flower of rare beauty; they like loamy soil, in which they will do in almost any position, but they are finest in cool and damp places, though they do not flourish in the very coldest of our soils and climates. Martagons make no stem roots, rooting only from the bulb, they need not therefore be planted deep." My experience differs from Miss Jekyll's. This garden is in Leicestershire, a very cold county, and is situated over 500ft. above the sea. The soil is a somewhat stiff and cold one, especially where the Martagons flourish, and they seem to bloom equally well every year irrespective of weather and, as I have already mentioned, their roots descend here to the very bowels of the earth. If this note is not already too long, may I mention the remarkable fruiting and ripening of seeds and shrubs generally considered delicate in this climate. *Chimonanthus fragrans* has been covered with large fruits containing ripe seeds, and is now (January 5) full of bloom. *Amygdalus macrocarpa* also has a large crop of fruits all ripened, with very hard shells, but bitter to the taste. *Staphylea* has also seeded abundantly and *Magnolia Soulangeana*, though alas! I did not realise it till too late, and the seeds became decayed owing to the recent heavy rains. *Halesia carolina* (Snow-drop Tree) has been equally fruitful. Curiously enough, the Walnuts, which were most plentiful, have all proved useless to eat, the kernels being quite rotten.—ELLEN MURRAY SMITH, *Market Harborough*.

CAMPANULA HAYLODGENSIS.

IN THE GARDEN of December 30 last, Mr. Cecil M. Bailey writes of a *Campanula* which he has under the above name as of "delicate growth and trailing habit" with "pretty violet blue flowers" which he describes as "small." It is evident that he has not got the true *C. haylodgensis*, which has very large and wide-open bells for its size, and these are a lovely pale porcelain blue. Nor could this excellent hybrid be called a trailer. With us, at any rate, it makes a tufty growth and shews no inclination to trail. The leafage is a bright green usually tending to a yellowish tint.—J.

C. haylodgensis is obviously a hybrid of *C. isophylla*, and accordingly not too hardy inland. Our correspondent has well described its appearance.—ED.]

AN EARLY RHODODENDRON.

DURING the winter months, where situations and soils permit, one may look forward to the flowering of that cheering shrub, *Rhododendron Nobleanum*. Among the numerous early-flowering varieties it is undoubtedly the first to blossom, and produces a magnificent and effective show of rosy crimson flower trusses. The blossoms often have a deal of inclement weather to face—occasionally severe frosts, and frequently strong winds. Care is therefore needed when

planting to select a fairly sheltered position. A thin surrounding of deciduous trees would prove of great assistance and break considerably the rough winds. An easterly aspect, too, should be avoided. The first blooms this season were shewing in early November. They have been produced freely ever since, and the flowers last for many weeks. The trusses of this species are of medium size and on the bush are most effective.—R. F. LEGG, *Herts*.

FOR A COLD WALL.

THOSE who have a cold but prominent position on a wall to furnish could do much worse than plant *Garrya elliptica*. The male plant is, when laden with its beautiful catkins, most conspicuous from the middle of December for weeks onward. I enclose a photograph of a plant growing on a north wall taken at Christmas

GARRYA ELLIPTICA AT CHRISTMASTIDE.

before it was quite at its best, but sufficiently developed to shew how beautiful it can be in dark winter days.—H. C. W.

SAXIFRAGA MIRA.

I READ with much interest Mr. Clarence Elliott's note in your issue of January 13 re the above beautiful hybrid. I had the pleasure of seeing the plant when it first bloomed, as far as I can remember, in or about 1910, with one solitary flower of a rich glowing deep pink colour. Mr. Redman, Mr. Farrer's manager, was naturally very proud of it, and propagated it. The point I want to make, however, is the question raised by Mr. Elliott as to its parentage. In the pot was one of the yellow labels affected by the Craven Nursery, on which was written "*Ilacina* x *Lapeyrrousei*." In discussing this plant since with other growers of rock plants, some doubt was thrown as to this cross producing the characters found in *Mira*. Mr. Farrer kindly gave me a rosette, which is now a nice little plant; but it has not altered in colour, nor can I imagine there were two plants in the first flowering specimen I saw. I can only surmise that, in propagating, some latent grace has been developed. In any case

either form or colour is a jewel, and well worth securing.—F. O. WALKER, *Annas Bank, Camforth*.

THALICTRUM ADIANTIFOLIUM AND ITS HARDINESS.

AMONG the various species and varieties of *Thalictrum* the dainty-leaved *adiantifolium* is sometimes lost sight of, and others like *T. T.*, *Delavayi*, *glaucum* and *aquilegifolium purpureum* are grown instead. As its name implies, it much resembles in foliage the tender Maidenhair Fern. The foliage is, accordingly, valuable for cutting for indoor decoration. Of the Meadow Rue it is, possibly, the least hardy, and to ensure it going safely through the winter I usually mulch the crowns with coconut fibre in late autumn, which is all they need. It may not be generally appreciated that *T. adiantifolium* is best suited when planted in partial shade, as under a pergola for instance, otherwise if fully exposed to the sun

the leaves soon begin to wither. The chief value of this variety lies in its fragile and beautiful foliage, and not in the blossoms, which are comparatively insignificant.—W. LINDERS LEA.

[It had never struck the Editor that *T. minus adiantifolium* was anything but entirely hardy. Would other readers please give their experience on the point.—ED.]

EARLY STRAWBERRY RUNNERS.

I SEE in your issue of December 30, 1922, the Rev. G. H. Engleheart writes on the subject of planting rooted runners of Strawberries from maiden plants in July for fruiting the following summer. I have always planted on this plan in my own garden, but for the last ten years have had no garden. I now want to start a Strawberry-bed next July or beginning of August, but am at a loss to know how I can get the rooted runners early enough, for, as your correspondent says, the nurserymen will never send them out till much later, thereby wasting a whole season. Could you tell me where I can procure three or four dozen rooted runners next July. I should like a good early sort—perhaps Royal Sovereign—and a later kind. I shall be very grateful if you can help me.—(Mrs.) J. W. MAITLAND KING.

FOR INDOOR DECORATION.

I WONDER whether your readers have tried using the berries of the Snowberry (the clustered fruit variety) and of *Cotoneaster Simonsii* together for house decoration. They have given us great pleasure. The readers of *THE GARDEN* who do not already do so should grow *Crocus Tommasinianus*, *speciosus* and *zonatus*. They are delightful. *C. speciosus* increases fast, sowing itself freely here and there and yet never encroaches. *C. zonatus* was in bloom in the grass at the end of November last.—E. A. STURGE.

THE ASTILBES.

ONE wonders why these telling and graceful plants are so seldom mentioned in gardening papers. Is it because the average grower of herbaceous plants thinks of them only as plants for the waterside—water lovers pure and simple? Such was my idea of them until August last, when I had the pleasure of visiting the gardens of Mr. Gerald Garnet at Wyreside, near Lancaster. There I saw the *Astilbe* growing round the edge of a shallow pond, but these were only the cast-outs from a lovely set growing on the north border of the walled-in garden. Beyond preparing the border well, prior to planting, these plants get no

special attention, and yet they were a mass (I might almost say a *mist*) of bloom from 18ins. to 5ft. or 6ft. high, and ranging in colour from white, as *Grandis*, through pink, as *Gruco*, to deep red, as *Salland*, with other shades of rose or pink. Plants of even the newest varieties are very reasonable in price, and should be tried.—T. O. WALKER.

NARCISSUS NOTES.

IN *THE GARDEN* of September 23, 1922, on page 480, Mr. Jacob has an article on Daffodils. I also am interested in them. He says *Phyllida* is an *Incomparabilis*, which I believe is correct. When, however, he says that Bath's, now hold the stock of it, he is not correct, as a year ago I exhibited a vase of it both at Wellington and Lower Hutt. This year I again exhibited it at Marton Show. Mr. Mason, nurseryman, of Feilding, saw it on my stand and remarked what a good thing it was. I have had *Carnation* some years, but it has not bloomed yet. Bernardino I sent to Mr. Grindrod, Auckland, and he wrote to say that the blooms did not open with him. I have no trouble with it myself, however, and can depend on every bloom to open. At its best it is very fine and "taking" on a stand.—ROBERT GIBSON, *Mania, New Zealand*.

THE AWARD OF GARDEN MERIT

THE following plants received the Award of Garden Merit on November 27, last:

STRANVÆSIA UNDULATA.

Evergreen shrubs are always valuable in the garden, and when to the winter green of their foliage they add pleasant flowers in summer, bright red fruits in autumn, and brilliant dying tints to their leaves, they are particularly valuable. All this one finds in *Stranvæsia undulata*. Its long-oval, glossy green leaves, sometimes but not always undulate at the margins, turn bright red before they fall, but not all at once. Here and there on the bush are a few red among the green almost the year round. It bears groups of small white flowers at the tips of the shoots in June, and though these are rather fleeting, they help to keep the shrub border bright when the more commonly grown shrubs are passing. In autumn their place is taken by brilliant groups of red haw-like fruits, fortunately not so loved of birds as so many of our autumn fruits are that vanish in a day just as or even before they are ripe. The bush is of rather open habit, so that its characters are easily seen, and it grows to a height of 6ft. or 8ft., and possibly eventually even taller.

Like so many of our beautiful shrubs, this is a native of Western China, whence it was first introduced by Mr. E. H. Wilson, who in 1900 sent seed to Messrs. Veitch. It appears to present no difficulty in cultivation; it seems not at all particular as to soil so long as the drainage is good; it is perfectly hardy, having withstood unharmed the severe winter of 1917 at Wisley; and is altogether a great acquisition among hardy evergreens. *S. undulata* was figured in the *Botanical Magazine* at t. 8418.

PYRACANTHA GIBBSII.

No trees or shrubs have more justified in 1922 their inclusion among garden plants than the well known coral red *Pyracantha coccinea* (or *Crataegus Pyracantha* as it is still often called) and its beautiful variety *Lalandei* with larger, more orange fruits. That came to us from Asia Minor and South Europe, but China has much

more recently yielded some beautiful shrub, apparently nearly related to the Nepalese representative of the genus, *P. crenulata*, but sufficiently distinct to warrant separate names, at any rate in gardens. It is difficult to say which is the most beautiful of these new-comers, and not all are yet widely known, but among them *P. Gibbsii* will certainly hold its own. Quick-growing to about 10ft. in height, with glossy dark evergreen foliage considerably larger than that of *P. coccinea*, making a tall, rather fastigate bush, flowering abundantly just after the Hawthorn ceases with dense bunches of white flowers, and never failing to bear great bunches of brilliant scarlet fruits as large as peas and contrasting beautifully with the foliage from October to December, this is a species worthy and capable of filling a place in any ordinary garden and in any part of Great Britain. The seeds grow freely, and may give rise to forms differing somewhat in the shape of the leaves, the exact shade of the ripe fruits and the precise time of ripening, but all alike worth growing; and if it be desired to propagate any one of the forms it may readily be done, either by cuttings or by layers.

RUBUS BIFLORIS QUINQUEFLORUS.

Many Rubi have come out of China, and some have little perhaps to recommend them for our gardens, but the subject of this note is not one of the latter. It is a striking plant, robust and handsome and graceful in habit. It owes its value to the remarkable stems, which are covered all over with a thick coat of wax so that they look as though they had been whitewashed, and strike a note in the shrub border which is almost unique in its effect. The canes reach about 10ft. in length, but arch over and root at the tip. This habit makes them easy to propagate, and the palatable fruits are also freely produced and seedlings appear to come true. The plants are best treated in the same way as summer-fruiting Raspberries, old canes being cut out after flowering about August, leaving the strong young canes for their winter effect. The plant is all the better for liberal treatment.

SEAWEED AS A FERTILISER

FROM the earliest days of our agricultural history, farmers, of northern lands in particular, have used seaweed as a manure in the raising of general crops, and there are many to-day, among whom are some of the most intensive cultivators in the world, by whom seaweed is held in the highest esteem. Yet, although we are an island people, only a comparatively small, almost negligible, proportion is used of that vast quantity of wrack which grows or is cast up on our shores and on the banks of tidal waters.

That seaweed is worth the hauling and the incidental labour involved is proven not only by the fact that it is used so largely by the Channel Islanders, Scottish Potato growers and others, but there are progressive farmers and market gardeners who find that it pays them to carry this material by motor tractor or water long distances inland. Analysis bears out the testimony of practical users that seaweed is as rich in nitrogen and potash as an average sample of farmyard manure. Indeed, it contains more potash than the latter, and its nitrogen, if slower in its action than that of dung, is more durable as a plant food.

The only fertilising elements of importance in which seaweed is deficient are phosphates and fibre, or humus. The former it is not difficult to supply and, as for the fibre, the weed partly compensates for the absence of this by its power of quickly reducing any other vegetable matter with which it comes in contact into humus. Thus, where seaweed is mixed with raw vegetable refuse, or manure, it will accelerate decay and render such matter of use to plant life in a very much shorter time than if the latter were left to the ordinary processes of decomposition, and in this respect it is better than lime, inasmuch as it does not destroy humus as the latter will.

Seaweed also has what one may call a mechanical effect upon the land. If it is used for light, sandy soils, which are liable to become very dry in summer, it will materially assist in the conservation of moisture. Soil pests dislike seaweed, and there are many noxious weeds which disappear from farms regularly dressed with it, while the seaweed in itself carries no weed seeds or spores of disease to the land as farm manures are liable to do. Though there is hardly a crop to which seaweed will not prove beneficial, particularly on light land, it has, in my own experience and that of others, proved especially good for the Brassicae (including Turnips and Kohl Rabi), Potatoes, Beet, Mangolds and Carrots. It has also been used with excellent results in fruit culture.

Seaweeds vary a good deal in their manurial value, the broad-fronded *Laminaria* and the common black *Fucus* (Black Tang) of the rocks being the most useful. Spring-gathered samples are richer in plant foods than those taken at any other season. Practical growers who employ wrack usually plough it direct into the soil in spring or autumn, according to locality. Others stack it in heaps or mix it with farm manure and other vegetable matter as suggested above; but there is no doubt that seaweed, like any other organic manure, loses much of its fertilising value from exposure to rain.

Of the fresh weed it is customary among those who use it regularly to apply 10 to 15 tons per acre to leguminous crops and 30 to 40 tons for Potatoes, roots or Brassicae. Experiments made both in this and other countries show that superphosphate given with seaweed has given highly satisfactory results. A. T. J.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Cauliflowers. Seedlings from the autumn sowing will have been pricked out in cold frames or boxes, and to prevent the plants from becoming staved in the latter they should be potted off in 4in. pots, using a mixture of loam and manure from a spent mushroom-bed. Over watering must be guarded against, and the plants ought to be grown as hard as possible by admitting air and removing the lights whenever the weather is favourable. Another sowing should be made in a cold frame or cool greenhouse, selecting an early maturing variety such as Early London or First Crop. Early Cauliflowers constitute an important crop in many gardens because at that time vegetables are rather scarce.

Rhubarb.—Apples are plentiful this year, so there has been no necessity to be in a hurry with forced Rhubarb. Now, however, a few roots may be introduced to a warm greenhouse or cellar. Under the stage of the former is an excellent place. Cover the roots with soil from the garden and keep it moist.

Onions.—The first sowing of a good form of Ailsa Craig may be made in boxes of loamy soil 4ins. or 5ins. deep. If the boxes are placed in slight heat, they should be moved to a cooler structure when germination has taken place and kept near the glass to keep the seedlings sturdy. A cool Peach-house or cool pit is best for general purposes where growth will be slower, and the plants will be ready for their permanent quarters in March without the trouble of pricking them off in boxes or frames.

The Flower Garden.

Bog Plants.—Where ponds, lakes or pools running through a rock garden exist, many plants may be successfully grown on the sides or margins which are often referred to as bogs. Among the finest plants for such places are the various coloured Iris *Kämpferi*, *Astilbes*, the bold *Saxifraga peltata*, *Rodgersias*, *Primulas* of the japonica type, the rich golden Marsh Marigolds and others. For the side of a lake, *Gunnera manicata* and *G. scabra* are to be strongly recommended.

Hollyhocks.—These stately plants should find a home in every garden, and if treated more or less as annuals the disease does not appear to be so rampant. Those with double flowers are very fine, but for grace and elegance the single kinds take first place. Seeds should be sown in well drained pans containing a mixture of loam and leaf-mould. Sow the seeds thinly and cover with fine soil, and germination will soon take effect if the pans are placed in a temperature of 60°. When large enough, pot off singly or prick out in boxes, and when they are fairly well established harden off gradually. Do not over-water the roots, and when the plants are arranged in a cold frame admit plenty of air. An open site should be chosen for their flowering quarters.

Verbenas.—Among Verbenas there are several choice and distinct colours, and most of the plants come tolerably true from seed. The giant forms are very effective for beds and borders. Seeds of these charming plants may be sown from now until the beginning of March. Place the pans in a warm greenhouse, pot off the seedlings when ready, and grow on as cool as possible until May, when they should be transferred to the beds.

Fruit Under Glass.

Vines. In the early vineery the shoots will soon need tying down to the wires, and such work ought not to be delayed. If the shoots are allowed to come in contact with the glass and sharp cold weather sets in, they will probably be injured. Each growth will need pinching, but this must be done in accordance with the space to be filled. As a rule each shoot is stopped at the second joint beyond the bunch of fruit. The later Vine rods will need pruning and cleaning, and the house ought thoroughly to be cleansed and the walls lime-washed. Prune the growths back to two eyes, free the rods of all loose bark, and then wash them with a strong solution of Gishurst Compound. If mealy bug is present there is nothing better than the Vine Rod Insecticide, which must be applied when the Vines are dormant. When growth begins and the house is warm and moist a sharp watch must be kept for mealy bug and every one destroyed.

The Hardy Fruit Garden.

Wall Trees.—The pruning and tying in of the trees on walls should be proceeded with when the weather is favourable. Established trees of

Peaches, Nectarines and Morello Cherries should have the old fruited wood cut away and replaced with well ripened young shoots. The beginner must guard against over-pruning. It is best to detach the whole of the tree from the wall, and all the old shreds and tying material should be burnt.

L. W. PATSON

(Gardener to W. R. Lysaght, 1sq.).

Castleford, Chesham, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Jerusalem Artichokes require a long period of growth for their full development, and as they are perfectly hardy and start into growth early the tubers should be planted as soon as the soil is in working condition. A moderately rich soil is most suitable for this crop. Select rather undersized tubers and pare away all the eyes except the main one and plant in drills 2ft. apart allowing 15ins. between the tubers in the drills.

Lettuce.—Sow a pinch of seed of some small early variety such as Tom Thumb or Early Ohio, and germinate in a moderately warm structure.

Cauliflowers.—Make a small sowing in a pan or shallow box and germinate as advised for early Lettuce. When germination has taken place and water is required apply by partially immersing the pan or box as a preventive of damping, which is the enemy to be guarded against. Snowball and Early Erfurt are suitable varieties for this early sowing.

The Hardy Fruit Garden.

Bush Fruits.—Take advantage of suitable weather for forking over the ground around Gooseberries, Currants and Raspberries. If manure has not already been applied, the omission should be made good prior to commencing forking operations. Failing some form of farmyard manure, a dressing of bonemeal or even soot may be substituted. A slight dressing of ground lime will also prove beneficial.

Fruit Trees in Grass.—Where the grass has been allowed to cover the entire surface, it will be found beneficial to scarify the surface for some 3ft. round the stem of each tree and slightly to fork over the soil prior to applying a mulch of half-decayed farmyard manure. This system has several advantages; it aerates the soil, feeds the trees and encourages the fibrous roots to keep near the surface.

The Flower Garden.

Bearded Irises.—The Iris has come into its own during recent years. The Bearded section may not be the most aristocratic of the genus, but it has forms of beauty denied to some of the other sections, and being easy of culture it can most readily be recommended to the average cultivator. Like many other plants, these Irises shew to best advantage when grown in masses. An Iris border is a source of interest and pleasure, and the next few weeks will be a suitable time for starting one. These Irises are not very particular either as to soil or situation. Do not plant deeply, as success largely depends upon the ripening of the fleshy rhizomes. In order to extend the flowering period the front of the border may be planted with a variety of the smaller bulbous plants, while the back line may be interspersed with *Iris sibirica*, *Hyacinthus caudatus*, *Montbretias* and *Gladioli*, the foliage of all of which harmonises with that of the Irises.

Jasminum nudiflorum.—So far as my observation goes, this welcome winter-flowering climber has proved very precocious this winter. As soon as it has gone out of flower it should be pruned. As it flowers on the previous year's wood, the shoots which have just furnished the bloom should be cut away, and it too thick some

of the shoots formed during the summer of 1922 should be thinned out.

Cotoneaster Simonsii makes a beautiful hedge plant with its abundant crop of orange red berries, and as it is all but absolutely hardy it may be planted without hesitation in any district of the country. It is also very effective as a wall plant.

Fruit Under Glass.

Melons.—Where an early crop of Melons is desired a sowing should be made within the next week or so. Sow singly in small pots filled with loam plus a dash of old hot-bed manure, plunge in bottom-heat where a temperature of 65° to 70° is maintained. For this early sowing use a free-setting variety, such as Hero of Lockinge.

Fruit Trees in Pots. For economic reasons many owners of gardens have converted part of their plant-houses into fruit-houses. Many of these houses are quite suitable for the culture of fruit trees in pots. Those who have fruit trees in pots plunged out of doors should now bring them inside. Before doing so free the pots of weeds and thoroughly wash them. Remove rim, or pins, of the surface soil by means of a hand-fork or a pointed stick and replace with fresh loam mixed with a little bone-flour. Apply no heat except to exclude frost, meantime ventilate whenever bright sunshine occurs.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

EDITOR'S TABLE

Cytisus racemosus.—We have received from Mr. H. Reynolds, Scraby Hall, Great Yarmouth, sprays of *Cytisus racemosus* (syn. *C. fragrans*), from a bush growing outside. The plant we understand is growing at the south end of a low span-roofed house and planted practically in the side of the pathway. We further learn that the plant has stood in its present position two winters without any protection whatever, except that afforded by the end of the house. The bush has been in flower since the end of September, but the recent heavy rains have somewhat damaged the blossom.

Trials at Wisley, 1923.—The Royal Horticultural Society will carry out at Wisley during 1923 trials of Dwarf Tropaeolums; Sweet Peas of carmine, deep pink, cerise, salmon and orange shades, Brussels Sprouts, Kales, Carrots (in open), Climbing Beans, Onions Vegetable Marrows and Cucumbers. Seeds of these plants should reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey, on or before January 31, 1923. Goods: Horsley Station, L. and S.W. Railway.

Our next issue (that for February 3) will be a Special Novelty Number. Many valuable new plants and strains will be described, and a number illustrated.

Answers to Correspondents

FLOWER GARDEN.

DAHLIA LEAVES CURLED (A Hong Kong Reader).—In the absence of specimens it is impossible to say whether insects are the source of the trouble complained of. It is commonly due, however, to some cultural error, especially connected with the water supply, in its relation to temperature changes. Cold nights are particularly liable to cause difficulty in regulating the amount of water required.

NAMES OF FRUIT.—J. W., Coventry.—Apple Foster's Seedling.

NAME OF PLANTS.—S. H. B.—*Eucalyptus Gunnii*.—H. Rob.—1, *Cotoneaster frigida*; 2, *Cotoneaster Simonsii*; 3, *Forsythia* sp., probably *F. suspensa*.

You can't Dig a Garden—

with good intentions and a hairpin. There has to be some honest spade-work.

You can do your digging and weeding with anybody, but you have your little weakness like the rest of 'em! You like to *look* as though you'd done it. A little perspiration, and good honest dirt thick up to the elbow!

Well, and why not? Just walk about a little where the neighbours can see you, and then—KIT.

KIT soap will clear every atom of dirt, grease, oil, paint or tar out of your hand, and will do it nearly twice as quickly as anything else. It is a nice "spready" sort of soap, so you need only a little. The tin is blue and orange (the handy shape and the handy size), and the lid comes off just when you want it.

Keep a tin in the house for cleaning after "odd jobs."

Price 6d. per Tin.

THE BOY'S OWN AQUARIUM and THE BOY'S OWN BOOK OF PETS, two booklets by Frank Egan, B.A., F.Z.S.; full of practical hints and useful information for parents and boys. Published at 9d. each, by post 11d., at the Offices of "COUNTRY LIFE," LTD., 20, Tavistock Street, Covent Garden, W.C.2.

"Prepare for the Spring."

Be ready this year for the cold winds and frosts which take toll of your seedlings, young plants and fruit crop, unless you take steps to keep them off.

"WINDOLITE"

will do this at a cost that will be repaid by the extra yield of the first season's crop.

"Windolite," like glass, keeps out cold and wet, but lets in light, whilst plants thrive under it. Unlike glass, however, "Windolite" can be bent, but not broken, can be cut with scissors and fixed easily to the lightest of framework.

With "Windolite," no skilled labour is needed in making cloches, screens and hand-lights of any size or shape, which in use are strong, light and handy, but, when not wanted, can be put away without fear of damage.

If your local dealer does not stock, we shall be pleased to send any length from one yard upwards post free, on receipt of cost.

BARR'S CHOICE FLOWER SEEDS

A few Novelties and Specialities for 1923.

ANCHUSA italica Lissadell, a beautiful border plant producing large flowers of a clear <i>Gentian-blue</i> , h.p., 5ft.	Pkt. s. d. 2 6	MYOSOTIDEUM nobile , the <i>Giant Forget-me-Not</i> of the Chatham Islands bearing large corymbs of beautiful <i>blue</i> flowers edged <i>white</i> , 1½ft. Very scarce	Pkt. s. d. 2 6
ANTIRRHINUM . New <i>Giant Strain</i> . Flowers of wonderful size, plants of tall and vigorous growth.		MYOSOTIS , Barr's <i>Alpine Blue</i> , the richest blue of all <i>FORGET-ME-NOTS</i> , forming compact bushes literally covered with heads of lovely <i>intense deep blue</i> flowers, and producing a most striking effect in the flower and rock garden, h.p., 9in.	1 6
Copper King , flowers <i>rich blood-crimson</i> with <i>fiery red</i> lip, very showy and attractive, 3ft.	1 6	PAPAVER nudicaule "Pearls of Dawn," a most lovely new strain of <i>ICELAND POPPIES</i> , producing satiny crinkled flowers of delicate shades of <i>pink</i> with <i>orange</i> or <i>salmon</i> glow, <i>salmon</i> shaded <i>blush</i> , <i>orange</i> shaded <i>cream</i> , <i>rose</i> shaded <i>pink</i> , etc., h.p., 11in.	1 6
The Rose , a very charming colour, beautiful <i>old-rose</i> with <i>yellow</i> lip, 3ft.	1 6	POINCIANA Regia , the <i>ROYAL PEACOCK FLOWER</i> , a tropical tree, native of Madagascar, producing <i>bright scarlet</i> flowers striped <i>yellow</i> . It thrives in countries like South California, Bermuda and the West Indian Islands. Seed saved in Queensland, Australia	2 6
Mixed Colours , containing many varied and beautiful colours; splendid border plants, 3ft.	2 6	POPPY , New <i>Double Queen Poppies</i> , a lovely new strain of hardy annual poppies of the Shirley type, but flowers double and semi-double, of the most delicate and brilliant colours, including <i>white</i> with <i>salmon</i> , <i>pink</i> , or <i>crimson</i> margin, <i>orange-salmon</i> shaded <i>white</i> , <i>fiery rose-scarlet</i> shading down to <i>white</i> , <i>cherry-red</i> shading to <i>white</i> , <i>brilliant scarlet</i> with <i>white</i> centre, etc., all showing <i>yellow</i> anthers, 2ft.; valuable for cutting, h.a.	1 0
AQUILEGIA , Barr's New <i>Rose and Scarlet Shades</i> , extra selected strain, very beautiful large flowers, mostly with long spurs, colours <i>rose-scarlet</i> and <i>rose</i> to <i>amaranth-pink</i> with <i>white</i> or <i>yellow</i> corolla, h.p., 2ft.	2 6	SCHIZANTHUS , Dr. Badger's New <i>Giant-flowered Hybrids</i> , a grand strain with very large handsome flowers, measuring 1½ins. to 1½ins. across, in great variety of colour and markings, <i>roses</i> blotched <i>salmon-red</i> , etc., <i>ruby</i> blotched <i>maroon</i> and <i>gold</i> , <i>dark blue</i> blotched <i>maroon-purple</i> , etc., h.h.a., 11in.; splendid plants for greenhouse decoration or flower border	2 6
BEGONIA , New <i>Narcissus-Flowered</i> , a remarkable new race of tuberous-rooted Begonias, flowers resemble in shape a <i>DOUBLE TRUMPET DAFFODIL</i> , the inner petals being joined into a large corona with petals elegantly waved and frilled at margin; the colours range from <i>light</i> to <i>dark yellow</i> , <i>orange</i> , <i>buff</i> , <i>blush</i> , <i>rose</i> , <i>dark red</i> and <i>scarlet</i> . About 60 per cent. of the seedlings come true to form	2 6	STREPTOSOLEN Jamesoni , a lovely cool greenhouse shrub of elegant habit, bearing corymbs of showy <i>brilliant orange-yellow</i> flowers, 3ft. to 4ft.	1 6
CALENDULA ORANGE KING , Barr's Extra Selected Strain, intense glowing orange	1 0	SWEET PEA Beautiful New Varieties in Mixture, a wonderfully fine mixture containing some of the best newer sorts of Sweet Peas, which cannot fail to give satisfaction to buyers	1 0
CAMPANULA , <i>Telham Beauty</i> , a grand variety of <i>C. PERSICIFOLIA</i> , introduced by us, which at the Holland House Show on July 4th, 1916, was given the R.H.S. AWARD OF MERIT. Produces on long stems immense bell-shaped open flowers, beautiful <i>clear lavender-blue</i> , h.p.	3 6	VERBENA , Barr's New <i>Giant-Flowered Mixed</i> , surpassing all other Verbenas in size of bloom and variety of colours, which include a good proportion of <i>scarlets</i> and <i>roses</i> , producing a very decorative effect in flower-beds and borders; all the flowers have a <i>brilliant white</i> eye, which enhances their beauty, h.h.p., 1ft.	2 6
CANDYTUFF , Barr's "Brilliant Gem," a remarkably effective variety with flowers of a <i>brilliant deep ruby rose</i> , a beautiful plant for flower beds and borders, h.a., 1ft.	1 0		
CENTAUREA Cyanus Double "Silver Queen," a very beautiful double <i>white</i> cornflower which will be highly appreciated for cutting, h.a., 2ft. For this novelty we were given an AWARD OF MERIT, R.H.S., 1922	1 0		
CHRYSANTHEMUM , New <i>Large-Flowered Single Varieties</i> , a very decorative strain producing large flowers of many varied and rich colours; valuable for borders and pots and for cutting, h.h.p., 2ft.; seedlings of February flower outdoors in July	1 0		
DIANTHUS cæsius , Barr's <i>Rose</i> , a charming variety of the <i>CUPIDIAN PINK</i> producing semi-double <i>bright rose-pink</i> flowers richly clove-scented, a gem for rockeries, h.p., 8in.	2 6		
ECHIUM Wildpretii , a wonderfully striking biennial plant from the Canary Islands, producing a dense rosette of silvery silky foliage 1½ft. high, from which rises a handsome spike 2ft. or more long crowded with <i>purplish pink</i> flowers. Good pot plant for the sunny part of a greenhouse; in the Scilly Islands it grows freely outdoors	2 6

[FEBRUARY 3, 1923.]

SOME NOVELTIES and RECENT INTRODUCTIONS AMONG TREES AND SHRUBS

The Species and Hybrids noted in this Article are of proved Merit and in Commerce.

TO name and write something about all the very many hardy trees and shrubs of recent introduction would require several issues of *THE GARDEN*. All that has been attempted is to draw attention to a few of the most interesting and important.

Among the Witch Hazels, *Hamamelis mollis* is the finest of them all in foliage and flower. It is not only the most showy, with its rich golden yellow blossoms, but these are deliciously fragrant and conspicuously beautiful from December to February. Many readers may question the "novelty" of a plant first introduced in 1879, but it is still not too common in gardens.

Syringa Wilsoni is a beautiful hardy Lilac from Western Szechuen, with lilac pink flowers, forming a vigorous bush 10ft. or 12ft. probably eventually more in height. Like the named varieties of *Syringa vulgaris* it is a good town shrub. *Cistus Silver Pink* is a charming hybrid Rock Rose, said to be a cross between *C. crispus* and *C. cyprinus*. It was raised in the Winchester nursery of Messrs. Hillier. The clusters of silvery pink blossoms are freely produced during summer and the plant has passed the last two winters in the open with us unharmed.

There are at least seven *Magnolias* of recent introduction: *M. salicifolia*, *M. Wilsoni*, *M. officinalis*, *M. denudata elongata*, *M. Dawsoniana*, *M. Nicholsoniana* and *M. Sargentiana*. Of these the first two have already proved to be most valuable additions to our gardens. *M. salicifolia* is a Japanese species which was first introduced to Kew in 1906, though it was five years later (1911) before the first flowers were produced. It is a slender tree of upright habit, deciduous, producing the pure white flowers freely during April in advance of the leaves. *M. Wilsoni* is later in flowering, opening its fragrant blossoms during the second half of May and in early June. The pure white flowers are more or less drooping and as they have bright red stamens and carpels these will show prominently when the bushes are 6ft. or more in height, as is already the case in Cornwall. In

habit it is elegant, with twiggy branches, more so than *M. parviflora*, which species the blossoms resemble. *M. Wilsoni* is a native of Western Szechuen, China, and was introduced by Mr. E. H. Wilson in 1904.

Two *Styrax* species are deserving of special mention, *S. Hemsleyanum*, introduced from Szechuen by Mr. Wilson in 1900, and *S. Wilsoni*

from Western China in 1908. In habit the two form a marked contrast. *S. Wilsoni* has thin wiry branches, small leaves and small white flowers, produced freely on young plants less than 1ft. high. *S. Hemsleyanum* on the other hand is a vigorous, widely branched shrub or small deciduous tree 20ft. to 30ft. high, with prominently veined leaves 4ins. to 5ins. long and 2ins. to 3ins.

wide, and pure white fragrant blossoms an inch across. We have had no frost of recent years severely to test the hardiness of the majority of the newer Chinese shrubs, though some we know are tender, suffering even in mild winters. *S. Wilsoni* is one of these, but it is a delightful plant for those not favoured with a mild climate; it should prove a charming pot plant for a cool or unheated greenhouse. Cuttings made from half-ripe shoots root readily in a propagating frame during late summer.

A new hybrid Crab of outstanding merit is *Pyrus Eleyi*, produced from the Russian Crab, *P. Niedzwetzkyana*, crossed with pollen of *P. spectabilis*. The hybrid inherits the distinct reddish-purple hue of the mother tree in wood, leaf, flower and fruit. The blossoms, however, are richer in colour, bright vinous red, followed by dark red fruits the size of cherries. Young trees commence to flower early—trees at Kew in 1922 produced flowers and fruit two years after grafting.

Pyrus (Sorbus) munda var. *subarachnoidea* (4323 Wilson) is a white-fruited Mountain Ash collected by Mr. Wilson in Western Szechuen during October, 1910. It forms a large shrub or small tree up to 15ft. or 20ft. high with pinnate leaves and white flowers, followed by clusters of pearly-white fruits. It is a pleasing companion to the older *Pyrus (Sorbus) Vilmorinii* (syn. *foliolosa*), which has attractive rich rosy-red fruits.

Pyrus Arnoldiana is a hybrid Crab which originated in the Arnold Arboretum among seedlings of the Japanese Crab, *P. floribunda*, the supposed pollen parent being a form of *Pyrus baccata*. It has larger and more richly coloured blossoms than the parent, ruby red when opening changing with age to rich rose. Another hybrid Crab with *P. floribunda* as the

LILAC ROSE PANICLES OF SYRINGA WILSONI.

female parent is *P. purpurea*, which I first listed in the catalogue of Messrs. Barber et Cie of Orleans. The pollen parent is undoubtedly *P. Nidzwetzkyana*, as it has the vinous red colouring which pervades the wood, foliage and leaves of that species. *P. purpurea* is a very attractive lawn tree with rosy crimson blossoms followed by dark red fruits the size of Cherries. *P. tongkodes* is a very distinct addition to the ornamental Crabs in foliage and fruit. The leaves are irregularly lobed, the fruit rich yellow freely flushed with scarlet on the sunny side.

In recent years the evergreen *Pyracantha*s have been added to by the introduction of several very distinct shrubs from China. *P. Gibbsii* is even more robust than the popular *P. Talander*, forming an attractive lawn shrub, with white blossoms and scarlet fruits. The variety *yunnanensis* is distinguished by the later ripening of the lighter red fruits, a valuable character, for though not quite so large I have seen the bushes full of fruits during March. The var. *yunnanensis* is also readily distinguished by the broad, round-ended (obovate) leaves. *P. Rogersiana* was introduced by Mr. George Forrest from Yunnan in 1911. The small leaves and close growth of this *Pyracantha* make it a very distinct shrub. There is at Kew a beautiful lawn specimen 8 ft. in height and as much in diameter. The fruits vary from red to yellow, the type being regarded as the one with red fruits. Variety *aurantiaca* has orange and variety *flava* yellow fruits.

Buddleia alternifolia is a widely branched and vigorous shrub, producing during June quantities of rich lilac-purple blossoms on the growths of the previous year, so that one cannot prune it in March as is done with *B. variabilis* varieties. Introduced by the late Mr. Reginald Farrer from Kausu, the dainty yet luxuriant growth of this *Buddleia* is in marked contrast to the vigorous shoots of *B. variabilis*.

Potentilla fruticosa var. *Farrerii* is a distinct dwarf form of the yellow-flowered shrubby Cinquefoil, introduced, as the name suggests, by the late Mr. Reginald Farrer. Its distinctive value for the front of the border of choice shrubs, and the rock garden, is the freedom of flowering from early summer to late autumn. Another of the late Mr. Farrer's introductions and perhaps the best known is *Viburnum fragrans*. It is a deciduous shrub ultimately 8 ft. to 10 ft. high, with white or pink tinted blossoms. We shall have to give it a sheltered position for the flowers open in March, perhaps earlier in warm districts, though probably the exhibit which gained for this plant an award of merit from the R.H.S. on February 22, 1921, was opened under glass.

A. O.

HELIANthemum UMBELLATUM

In general appearance this dainty little shrub more resembles a small-leaved Rosemary than the general run of Sun Roses. It is a native of the Mediterranean region, and nearly two hundred years have elapsed since it was first introduced, but it still remains quite a rare plant. It grows about 18 ins. high and is evergreen, bearing a profuse succession of flowers in summer for several weeks. The flowers are white with a patch of yellow at the base of each petal. Like all the Sun Roses they are of short duration opening in the early morning and dropping before sunset, but they make a great show for the time and are succeeded by a similar crop next day. It likes the sunniest possible position and a well drained soil of moderate quality, and is easily increased by cuttings.

A FRUITING SPRAY OF PYRACANTHIA GIBBSII YUNNANENSIS.

ABOUT SOME OF THE BEST NEW ROSES

THE Roses which are being distributed this season certainly include some of the best varieties sent out since the war. The beautiful golden Florence L. Izzard is unquestionably the most noteworthy. It is rightly classed as a Hybrid Tea, but shows unmistakable traces of the Pernetiana race in its shiny dark green foliage. The high pointed centre, however, proclaims the Tea blood; so does the slight but unmistakable fragrance. Mr. McGredy is to be congratulated on this glorious variety, for which there will doubtless be a big demand.

Another yellow Rose of considerable importance is Mary Merryweather. The flowers of this variety inevitably call to mind the invaluable Lady Hillingdon, but it is considerably paler in colouring; moreover, the buff which blends with the deep orange yellow of the older variety is absent. The new introduction is of stockier habit than Lady Hillingdon and a good doer. It is being distributed by Messrs. H. Merryweather and Sons, Limited, and is likely to prove a first-rate bedding Rose.

Yet another beautiful variety of yellow colouring is to be found in Lucile Barker, one of Mr. Elisha Hicks' novelties, which has orange fawn blossoms shading to pale orange. This is a comparatively small Rose, but beautifully shaped. Every bud would make a buttonhole!

In Lady Verrey, also sent out by Mr. Elisha Hicks, we have what might be called a shell pink Liberty. Rather a thin Rose, it should be admirable for decoration indoors or for bedding. Elsie Beckwith, a novelty of Messrs. G. Beckwith and Son, has been described, not inaptly, as a carmine rose Richmond. It bears long, clean stems and should be first-rate for cut flower, whether grown indoors or out.

Mrs. Henry Bowles has beautifully formed pointed blossoms of warm rosy pink colour. The petals are slightly rolled, and it is pleasantly Tea-scented. A gold medal was awarded to Mr. W. R. Chaplin for this Rose at the last Summer Show of the National Rose Society. From this very "rosey" Rose we will turn by way of contrast to Messrs. Ben Cant's brilliant Lady Roundway, which in the bud state is heavily flushed with cardinal red. The expanded flowers are also very striking, being rich coppery orange shaded with deep rose. This is an exceedingly fragrant Rose, and if not a very shapely one—it is on the flat side—its glorious colouring largely covers the want of form. Another beautifully coloured newcomer is Souv. de R. B. Ferguson, a combination of tones of golden fawn and apricot and warm pink. It is a strong, healthy grower with healthy dark green foliage. Of no great size but very fragrant, it should be a really valuable bedding Rose. It was raised by Mr. Wm. Ferguson.

Messrs. Ben Cant's Phoebe forms a magnificent rather square-looking blossom of primrose shading and sweet scented. It is unquestionably a fine exhibition variety and excellent under glass. A gold medal Rose.

Mr. George Prince is responsible for the beautiful Tea Rose Muriel Wilson, which, also of lemon colouring, is also fragrant. This should be an indispensable variety for under glass.

Mrs. H. L. Wettern is yet another of Mr. McGredy's production and, as might be expected of a Rose with such a name, is a first-rate variety. The blooms are of a particularly vivid shade of pink, high centred and shapely; the plant is a strong, vigorous grower and it is, happily, fragrant. Dewdrop, from the same raiser, is practically shell pink in colour at opening, passing off to rose

as the flower expands. Very strong growing, tree and prolific, it should be a useful bedding variety.

A useful trio of dark Roses include Arthur Cook and Lady Sackville, both from Mr. McGredy, and Captain Kilbee Stuart from Messrs. Alexander Dickson and Sons. Arthur Cook is of good size and rather nice form, albeit, like many crimson Roses, rather on the flat side, wonderfully and delightfully fragrant, and has good clean foliage. A fly in the ointment? Well, yes! Some of the

Messrs. Frank Cant and Co. send out Mrs. Harvey Cant, which is a fine large white variety, a little loose in the outer petals but otherwise first-rate. Very different is Westfield Star, milk white and pale yellow in the heart, reminiscent indeed of a very beautiful buttonhole Rose which is now probably out of commerce if not out of cultivation—Pauline Bersez. There is plenty of room for such shapely rather small Roses, but somehow they do not seem to "go" very well. Size is still a fetish with many.

Mrs. Hornby Lewis is a Rose of ample proportions and, apparently, Souv. de la Malmaison "Blood." It has good foliage and the blossoms, which, like those of Maréchal Niel, shew a tendency to "quarter," are chrome yellow in colour, delightfully shaded. This pleasingly fragrant variety is being distributed by Mr. Elisha Hicks. In Mr. McGredy's Mrs. Courtney Page we have a singularly attractive variety. Free blooming and of wonderful and exquisite colouring, which is a sparkling orange cerise with bright carmine shading towards the base. This is a most distinct variety with petals of great size and substance, a model in shape and formation. It is sweet scented and without question one of the finest and most superb Roses ever raised. Awarded the Gold Medal of the National Rose Society.

There are, of course, other new double Roses, but those mentioned probably include the pick. There are several new single varieties of undoubted merit. Most beautiful of all is undoubtedly Mr. W. R. Chaplin's beautifully fluted white Innocence. A good doer and fairly free to flower, this is surely one of the most beautiful flowers ever raised. From pure white to deep crimson—from the saucer-shaped Innocence to the almost hooded Vesuvius of Mr. McGredy. This last, however, is very free flowering and of wonderfully rich colouring. In form it might aptly be compared to the cupped female blossoms on a Begonia.

Nur Máhal, one of the Rev. Pemberton's novelties, is a semi-single Hybrid Musk variety which should make a handsome free bush. The colour is a deep rose, the flowers are of good size and freely produced. In

colouring and form and in the white streaks which mark some of the petals this variety recalls the old Cabbage Rose.

Two single Polyantha varieties are well worthy of notice. One is Messrs. Prior's Alice Amos with American Pillar colouring. This is very attractive. Its weakest point is the eye, the cluster of stamens being rather meagre. The other variety in mind is Laxton's Pink Delight of that salmon rose shade we call wild rose. This is a Rose everyone should try to procure. Indoors or out, it would be difficult to use it in the wrong place.

That beautiful white Wichuraiana rambler Snowflake is being placed upon the market this season by Messrs. Frank Cant. The flowers, which are pure white, are borne in large trusses. Probably not all the varieties mentioned will be in commerce this season, but most will be. R.

A PROVED VARIETY, ROSE MARY MERRYWEATHER.

blossoms have the unwanted bluish cast. Lady Sackville may be described as a freak Rose. Its blossoms, which are of medium size, are as near black as makes no matter. Before this variety, which is, by the way, fragrant, the old Prince Camille de Rohan must retire permanently from the field. Captain Kilbee Stuart is a "dark horse of another colour." This is of light, almost scarlet shade of crimson, but rich and velvety, and the foliage is on the light side. The petals are broad and shapely, and it has the old Rose scent. This is now a gold medal Rose.

There are many who like rose-coloured Roses. Such will rejoice in Bessie Chaplin, which is much of the La France type but less silvery in colour. It is up to exhibition standard, but will doubtless prove a first-rate garden variety. One of Messrs. Chaplin Brothers' novelties.

PROGRESS WITH THE DAHLIA

IT is rather too early in the season to pass in review Dahlia novelties for 1923. For the present we must be content to consider the lines upon which progress is taking place. The Star Dahlia has come into its own, and further progress is certain with this highly decorative type. The dwarf Mignon bedding Dahlias are not nearly so popular as they should be. Most gardeners nowadays grow a selection of Star or Single Dahlias to stop gaps in the middle of the herbaceous border as some of the early-flowering hardy plants go out of blossom, as well as a few tall Decorative sorts for further back. Why should not the Mignon type be grown for the front of the border, where gaps are more noticeable than elsewhere?

The Cactus Dahlia is not, and probably never will be, so free-flowered as the Decoratives or as the various Single types we have been discussing, but it has improved marvellously as regards carrying its flowers erect. Some of the more decorative varieties, too, carry their blossoms clear of the foliage. May the day be near when all new varieties do!

The Collarette type is very effective, especially when the contrast between petals and "collar" is pronounced. No doubt this section is destined to become yet more popular. There is no class more generally useful than the Pompon, but there is little room here for anything absolutely distinct. The huge Decoratives so popular in Holland, of which *Souv. de Gustav Douzon* may be taken as the type, are not particularly favoured in this country. They are rather too coarse and flaunting for most people. An entirely new type of large-flowered Dahlia is represented by *Rosella Amos*, here illustrated, which might fittingly be called *Chrysanthemum*-flowered. This was raised by Messrs. J. Stredwick and Son of St. Leonards, who have raised so many fine Cactus varieties. It is to be distributed in May jointly by Messrs. Stredwick and Messrs. D. Prior and Sons of Colchester. It is a huge flower, quite up to the size of the large Decoratives referred to, but much less "lumpy" looking.

The Pæony-flowered section is yet susceptible of great improvement. Most of the varieties are too shy or too invertebrate to hold their heads up, and a considerable number of very beautiful sorts considered on the merits of the individual flowers cannot produce the effect they otherwise might because the blossoms are not sufficiently clear of the foliage. The Miniature Pæony-flowered are a great improvement in this respect. No doubt they have been largely obtained from Single and Star forms of excellent habit. There is, however, abundant room for the large-flowered "Pæones," and it is to be hoped that many new varieties will soon be marketed with flowers as well displayed as on the best of the Minatures. It is not, after all, the weight of the blossoms which weighs them down or the huge Decoratives would also be "bashful," but such is by no means the case. A New Zealand correspondent, Mr. H. Goldie of Auckland, sent us during last autumn two pictures, one of which is reproduced herewith, of a new type of Pæony-flowered Dahlia which has originated with him. It is, as the picture shews, quill petalled, and if a race of similar character can be evolved they will, no doubt, be very popular for cut-flower work. Of their value in the garden it is impossible

DAHLIA ROSELLA AMOS.

to speak, but experience shews that it is possible to retain the character of the flower while perfecting the habit of any class of Dahlia. This first "quilled Pæony" variety the raiser describes as "straw, shaded buff and is quite striking." It was raised "from seed of a Pæony Dahlia, specially selected; the petals are of tubular form and the stems stiff, thus making for a good florists' flower."

The Camellia-flowered varieties such as Messrs. Cheal's *Crimson Flag* are invaluable in the garden. Very free-flowering, this variety—the best of the Camellia-flowered to date—is remarkably effective when bedded, especially when associated with one or other of the soft lemon yellow Mignon varieties. Decidedly there is room for many more really good Camellia-flowered sorts.

Whereas the Camellia-flowered is pre-eminently a garden form, the Miniature Cactus is above all suitable for cut flower. The white-flowered sorts are in great demand for wreath work, but white or clearly and cleanly coloured the varieties of this section are admirable for indoor decoration. Of moderate size—not too large even for table decoration and, for a double flower, exceedingly light and graceful, they may be used alone or in combination with single varieties of the Exhibition Single, Star or Mignon sections or, again, with some of the lighter and more graceful Collarettes.

Every Dahlia raiser knows that the possibilities of the flower are extraordinary. Many new "breaks" in beds of seedlings, not worth saving on their own merits, would, no doubt, with careful selection, be the progenitors of strains entirely different to any now in commerce, but probably the raisers are wise not to attempt too much all at once. There is, after all, much room for improvement in some of the sections already in commerce.

A NEW TYPE OF DAHLIA

NEW GREENHOUSE PLANTS

MESSRS. BLACKMORE AND LANGDON are, as usual, well to the fore with Begonia novelties. Among these the double fimbriata varieties are sure to find favour. Some of these remind one of the frilling of *Dianthus laciniatus*, but others—and these, in our judgment, are the more beautiful—are less congested in petal and retain the main characteristics of a good double camellia-flowered Begonia but with pleasingly “gaufré” petals notched at the edges. Tubers of these are offered as well as seeds.

Novelties in Basket Begonias include Golden Shower with flowers which when partly expanded are similar in colour to Rose William Allen Richardson, Stella of Fleur de Chrysanthème type and of a rather salmony tone of red, and Venus, a magnificent white variety. The flowers have, until fully expanded, a yellowish green cast which reminds one of the so-called yellow-flowered Cherry, *Prunus serrulata flore luteo pleno*. Messrs. Blackmore and Langdon also offer several fine new named double Begonias. These include one of the double fimbriata type, to which reference has already been made. This is named Mignon, and the colour is rosy cerise, the habit of the plant compact, and the flower admirable. In Hilda Langdon the firm believe they have the most beautiful double Begonia ever offered, which to those who know the quality of their productions is saying a great deal. The form is perfect, the size immense—flowers 6ins. and more across are common—and the colour a beautiful

rose pink, deepening to the centre. Lord Lambourne is another beauty with camellia-shaped blossoms, deep salmon orange, paling to the centre and retaining its colour when expanded; a large and substantial flower. Other novelties include A. H. Bunney, a frilled variety of reddish cerise shading, the flowers substantial and carried erect; Mrs. F. Bedford, a splendid bluish, flushed salmon; and Mrs. F. C. Calthrop, salmon pink, deepening to the centre and lit with golden tinting—a handsome flower, well held and very attractive. In John G. White the firm offer a fragrant double Begonia. The plant is free-flowering and of good habit, and the blossoms are bluish pink in colour.

Messrs. Dobbie and Co. of Edinburgh offer tubers and seeds of the new narcissiflora Begonias, which were illustrated in *THE GARDEN* for October 22, 1921, page 531. Narcissus-flowered is indeed no fanciful description if we assume the Narcissus in question to be the old double Van Sion. They are offered in shades of yellow and cream and also in red shades, while seeds are also obtainable. Messrs. Sutton's frilled Begonia Enchantment and the same firm's “Duplex” Begonias are mentioned on another page, since both are only offered from seeds.

Messrs. H. H. Maw and Sons of Pontefract have, in addition to their fine strain of *Primula obconica*, a really interesting novelty in Marguerite Guinea Gold. Not only is this very much deeper in colour than the ordinary yellow Marguerite, but it is remarkably compact in habit and very free-flowering.

Among the invaluable Perpetual Carnations there are several excellent novelties this season. Of these Messrs. Allwood Brothers' Chintz, which the raisers describe as bluish mauve ground flaked and speckled with claret, is quite one of the best. Many growers who do not as a rule like flaked Carnations were enthusiastic in its praise when it was exhibited in 1921. It was illustrated in *THE GARDEN* for December 10, 1921, page 624. Chintz is a very happy name for the flower and describes it much better than could any description. The firm, ivory-like petals suit the colouring to perfection.

Mr. Engelmann has a really good novelty in Goliath, which in the spring months often has 4ft. stems. It is a fringed and very fragrant variety with huge blossoms of a pale salmon pink colour. Another good novelty from the same raiser is Dora, which has fine substantial flowers produced in sufficient abundance to make it a profitable market sort. The colour is a clear salmon pink, just a trifle darker than the popular Lady Northcliffe. The calyx does not split.

Mr. Engelmann's other two novelties are sports from well known varieties in commerce. Cream Saffron is a distinct clean shade of cream sport from Saffron. The exact shade of colour is not matched in any other variety. Orange Sunstar is, as the name would suggest, a sport from Sunstar. The colour is an attractive deep orange with a few pink stripes.

British Perpetual Carnations are now quite equal to the American-raised varieties even as these latter grow across the water. With very few exceptions the American varieties are not, in Britain, nearly so good as those of British origin.

WHITE BASKET BEGONIA VENUS.

THE HUGE ROSY BEGONIA HILDA LANGDON.

"WHAT'S NEW" IN FLOWER SEEDS!

AMONG Messrs. Sutton's flower seed novelties the most interesting is unquestionably their new bedding strain of *Antirrhinum*. The plants attain a height of a foot or perhaps a little less under normal conditions and, having no central spike, produce admirable bedding effects. The spikes are close-pointed, but remain spikes, which can hardly be said to be the case with the Tom Thumb varieties. White, yellow, apricot, pale pink, bright pink, buff pink, cherry pink, orange-red, and the glowing orange-scarlet with a white throat the firm call Fire King. Many readers will know the variety called Sutton's Fire King Intermediate. The bedding Fire King is a little more "orangy" than that splendid sort. Needless to say, the Reading firm is still offering a full selection of varieties in the Tom Thumb, Intermediate and Tall sections.

Messrs. Sutton are making a speciality of what they have christened Duplex Begonias. The flowers have the large petals characteristic of the single types but in two or three rows. They are very distinct in appearance from the ordinary double Begonia, and will probably appeal rather to lovers of single than of double flowers. Messrs. Sutton also make a speciality of the beautiful frilled Begonia they call Enchantment, which comes true from seed. This is a golden yellow variety edged on the "frill" with bright rose.

Reading is almost as famous for its *Primulas* as for its biscuits. This season Messrs. Sutton are offering nothing absolutely new in large-flowered *Primulas*, though new and reselected strains are yearly put upon the market without any "blowing of trumpets," without, indeed, any note of the fact in the catalogue. The new Star *Primula* Symmetry, which was so much admired last year at Vincent Square, is now offered for the first time. It is deep rose pink, almost a crimson, and the flowers are so smooth and circular as rather to make meaningless the term "star." It has, however, the light graceful habit of the Star section, and is, moreover, a very robust easy doer. "S. and S." are also offering seed of their

Primula obconica Salmon Queen, which obtained an award of merit last Chelsea Show. It is a very beautiful and free-flowering sort with shell pink blossoms, and is quite a "new departure" with this flower.

There has of late been a revival of interest in the pretty and graceful *Cosmeas* (*Cosmos*) brought about by the introduction of early-flowering strains. Lateness to flower was the great drawback of the older strains, which were in other respects very desirable, both for garden decoration and cut flower. A further advance is marked this year. The beautiful anemone-centred doubles are this year offered by Messrs. Sutton in an early-flowering strain which will, they say, flower in ten weeks from sowing. Could anyone ask for more? Seeds are offered in white, rose, crimson or mixed.

Messrs. Barr and Sons, Covent Garden, always to the fore with seeds of hardy plants and shrubs, are this year offering seed of their magnificent *Campanula persicifolia* Telham Beauty with clear lavender blue flowers. Among a number of strains of choice *Aquilegias* (*Columbines*) the most noteworthy is perhaps Barr's Silver Queen, a long-spurred variety with white flowers faintly

PRIMULA OBCONICA, SUTTON'S SALMON QUEEN.

tinged, especially on the spurs, with rosy sapphire. Seed of that hardiest of New Zealand Flaxes, *Phormium tenax* Powerscourt Variety, is another outstanding feature of their list. This is a fine as well as a hardy variety, the flower-spikes not seldom reaching 14ft. *Primula pulverulenta* Annesgrove Variety is the deeper coloured pink form to which reference has often been made in *THE GARDEN*. It is at once more interesting and more vigorous than Mrs. Berkeley. Seed is also offered of *Primula chionantha*, one of the easiest and most beautiful of the nivalis section, in appearance something like a white *P. sikkimensis*. The rare *Primula seclusa* is also listed.

Of plants of shorter duration of which seeds are offered by the Covent Garden firm, mention should be made of *Statice sinuata* True Blue, with rich blue flowers in place of the usual lavender, and the new Double Queen Poppies, really a very true strain of double and semi-double "Shirleys." By the way, Messrs. Barr are offering the Shirley Foxgloves (*Digitalis*), a specially fine strain raised and selected, of course, by the Rev. W. Wilks. Other exceedingly interesting items are *Papaver alpinum* Shell Pink, said to come true from seed, and *P. orientale* Barr's New White. Oriental Poppies do not come true from seed, but a proportion usually do, and the remainder are commonly interesting and beautiful. These only represent a selection from some two hundred items of new and uncommon strains of seed.

Messrs. James Carter and Co. of Raynes Park offer long-spurred *Aquilegia* seed selected to rose and pink shades, which for some purposes should be very desirable; two new double *Clarkias*, a new crimson *Cyclamen* (Crimson St. George),

THE MANY COLOURED "JAPANESE MOUNTAIN" CHRYSANTHEMUMS.

a new Indian Pink (Double Fiery Scarlet), three new Gloxinias and a very fine new strain of Hollyhock. The flowers of this are not so full as with the "show" doubles, but the petals are prettily fringed and curled.

Messrs. Kelway and Son of Langport, famous the world over for Delphiniums and Gladioli, are "wholesale only" as regards flower seeds, but their special strains are obtainable from reputable seedsmen throughout England, many of them in the Langport firm's own sealed packets. Mignonette Perfect Model is recommended as the best on the market for pot culture and invaluable also outdoors. It is of sturdy, compact habit, and the huge spikes are well coloured. They also offer seed of their celebrated strain of perennial Gaillardia, certainly one of the finest in cultivation; of their even more famous Gladioli and of their new hybrid Lupins, either mixed or in separate varieties, namely, Belle of Huish, Canary, Coronation, Effective, Langport King, Phyllis Kelway, Prinrose Queen, Punchinella, Rod of Ivory and Somerset. Petunias, single and double, Pansies, Ryburgh Hybrid Poppies, Pyrethrums and Cinerarias are also offered by Messrs. Kelway, who are known as specialists in all of them. Messrs. Kelway are strictly wholesale, but if any difficulty is experienced in obtaining their seeds they will gladly supply the name of their nearest agent.

Messrs. Edward Webb and Sons of Wordsley have long been noted for their Schizanthus—Butterfly plants as some call them—and their new Giant Hybrids, containing, as they do, all shades and many combinations of colour from palest, pink to violet purple are exceedingly attractive for the greenhouse and also in a sheltered place, for bedding outdoors. Some of the dwarf strains especially are very handsome and succeed well bedded out. Those who have never tried this flower so might do worse than make a note of it. Among many other specialties of the Wordsley firm may be mentioned Sweet Sultans, which are at once beautiful, fragrant and admirable for cut flower. Messrs. Jarmans of Chard, Somerset, also have magnificent stocks of this splendid flower.

Messrs. Watkins and Simpson are a firm fairly familiar to the general public because their name so often occurs in lists of plants which have received an award of merit after trial at Wisley. They would doubtless be better known still were they not, like Messrs. Kelway, wholesale only. Their novelties are obtainable from most seedsmen and retail nurserymen. They are, this season, sending out three new Antirrhinums. Two are dwarf varieties (*natum grandiflorum*), these being Madonna, which the firm consider an improvement even upon their well known white sort Purity, and Radiance, of which the flowers are salmon rose, orange and terra-cotta, providing, in the garden, a rich glowing salmon red effect. The third variety is a tall one, and would be splendid for massing in shrubberies or elsewhere where stiffness is at a discount. The golden yellow central band merges gradually into the colouring of standard and lip, which is pinkish bronze. The individual flowers are fine, so are the spikes. Another interesting novelty offered by these Covent Garden wholesalers is the Japanese Mountain Single Chrysanthemum, to which reference has more than once been made by Mr. E. H. Woodall in our "Correspondence" column. These are single and very starry and neat in appearance, and are of many colours. *Clarkia elegans* in its various forms is fast becoming popular as a cut flower; indeed, the long, graceful sprays are nowadays often seen in Covent Garden market. "W. and S." offer this season a novelty called Ruby King, of ruby red colouring, which

should be a very useful addition. *Dahlia Stella*, which might be described as a single Cactus with no twisting of the petals; *Gaillardia Dazzler*, golden yellow and maroon red, and said to come almost true from seed; *Sunbeam Improved Iceland Poppies* and *Viscaria Tom Thumb Rosy Gem* are other novelties, besides half a dozen promising new sorts of Sweet Pea.

Messrs. Thompson and Morgan of Ipswich, always to the fore with perennial seeds, have an attractive list of novelties, including seeds of such beautiful Lilies as *L. regale* and *L. sulphur-gale*, Harkness's new Giant Iceland Poppy Tangerine, of which the name is fairly descriptive, Downer's strain and several other new strains of perennial Lupins now so deservedly popular. A new upright-growing Verbena called Royal Bouquet is indeed a novelty, inasmuch as the plant grows about 15 ins. tall and only 10 ins. or so across. When in bloom it makes a beautiful mass of colour, and it should be exceedingly useful for growing in pots. Those who grow the handsome tall perennial Toadflax known as *Linaria nacedonica* will wish to procure *L. m. speciosa Nymph*, which has cream-coloured flowers, orange yellow spot on the lower lip and the characteristic glaucous foliage.

Perry's Hardy Plant Farm, Enfield, offers a long list of perennial seeds of interest to all who like raising choice plants from seed. Among many uncommon plants to raise from seed we select, almost at haphazard, *Anemone Mollenderi*, *Geum Borisii*, *G. Mrs. Bradshaw* (a fine rock garden plant), *Incarvillea thalictrifolia*, *Iris sibirica* Perry's Blue (well known as the finest of the Siberian Irises), *Lilium Balfourianum* and *L. L. pardal-parryi* and *sulphur-gale*, also *Papaver orientale* Lord Lambourne.

M. H. Correvon of Chêne-Bourg, Geneva, specialises in seeds of alpine plants. There is no need to mention any particular "novelty,"

THE BEAUTIFUL AND FRAGRANT HARDY PRIMULA CHIONANTHA OFFERED BY MESSRS. BARR AND SON.

SUTTON'S EARLY DOUBLE COSMEA.

for most of the species offered are more or less uncommon and some exceedingly rare.

Messrs. Blackmore and Langdon's seed novelties in Begonias are referred to elsewhere. The Bath firm also offer seeds from their magnificent Gloxinias and Cyclamens, Primroses and Delphiniums.

Messrs. John K. King and Sons of Coggeshall are large growers of flower and vegetable seeds of many kinds, but especially Sweet Peas. Of these last they have four novelties this year, namely, Advance, white, flushed rich pink, throws many duplex flowers; Faerie Queen, salmon on a cream ground, well frilled; Powerscourt, said to be the largest flowered, strongest growing and best lavender variety to date; and Wild Rose, deep old rose touched with salmon orange in the standard.

Messrs. John Peed and Son of West Norwood are offering a splendid strain of large-flowered Streptocarpus hybrids, not only mixed, but in separate colours—pink, red, purple, white, and

white with purple stripe. Messrs. Peed's magnificent strain of Cockscomb is scarcely a novelty, but it is of outstanding excellence.

Messrs. Toogood and Sons, Limited, of Southampton, have several excellent novelties, including two new annual Asters, a new Ten-week Stock and several new Sweet Peas. Phlox Drummondii, Toogood's Salmon Queen, is perhaps the pick of the basket. This new salmon rose tint possibly provides, with the crimson and white strains now so widely used, as much variety as is really necessary in this very charming annual.

THE LATEST IN VEGETABLES

THE most striking novelties among vegetables this year are undoubtedly Messrs. Sutton's two new Dwarf Broad Beans, The Sutton and Sutton's Little Marvel, described (and The Sutton illustrated) in our issue for January 13, page 22. In addition to these new Beans Messrs. Sutton are offering a new dwarf second-early Pea—Sutton's Sensation. The haulm only attains a height of 2ft., the pods are handsome and very prominently borne in pairs, and the plant is of robust constitution. Seven and eight are usual numbers of Peas in the pod and the flavour is excellent. The new French Bean Sutton's Premier is a brown-seeded hardy and robust variety which produces pods as large as those of Canadian Wonder, but much more quickly. It is a fine-flavoured sort and continues in bearing for an unusual length of time. Messrs. Sutton's other novelty is Capsicum Golden Spire, which, while naturally of culinary value, is highly

ornamental. It should be very useful to those who wish to exhibit collections of vegetables.

Messrs. Webb's also have a new French Bean—New Bountiful—which is also an early, prolific and continuous bearer. The Midland firm are also marketing for the first time a new Potato—Webb's Renown—which is of excellent appearance and fine quality. It cooks mealy, is shapely enough for exhibition and its cropping properties, we understand, are excellent. The real worth of new varieties of Potato only time can prove. Let us hope it will be a worthy companion to the splendid Webb's Emperor Cabbage, so largely and so wisely grown by market growers.

Messrs. Dobbie and Co. offer a fine exhibition Celery in Dobbie's White Queen. It was raised by a Scottish exhibitor, who has won many prizes with it at leading shows. They also offer a special

re-selection of their Champion Scarlet Runner Bean. They differentiate this from the ordinary stock by placing xxx in front of it, a sign of

NEW MAINCROP POTATO, WEBB'S RENOWN.

distinction which may not be perfectly clear to some of their teetotal customers!

Messrs. Laxton Brothers of Bedford are, perhaps, best known to readers of THE GARDEN as raisers and growers of Strawberries and other hardy fruits, but they have, actually, raised some of the best Peas now in commerce. They are this season sending out Laxton's Progress, which Messrs. Laxton consider the finest Dwarf Pea they have raised. It is a fully wrinkled Marrowfat variety, containing, as a rule, nine or ten Peas in a pod. It is earlier than the well known Laxtonian, the pods are exceptionally dark coloured, and the Peas large and fine flavoured. The height is given as 1½ft. to 2ft.

Messrs. Kelways are distributing through their numerous agents Broad Bean Kelway's Upright Early Longpod. This variety is notable for the number of pods it bears at the base of the plant. The pods, even fully grown, are held erect, and the plants carry a very small amount of haulm. The Langport firm, curiously enough, also have a new dwarf French Bean which is reputed to be as fine as and earlier than Canadian Wonder. It is said to be both early and free cropping. The seeds are the colour of those of a newly burred horse chestnut and blotched with cream. In Kelway's Perfect Model the firm claim to have the finest Cucumber for exhibition yet sent out. The fruits, which reach a length of 24ins., are straight-sided and dark green in colour, and carry a beautiful bloom.

Messrs. Carters of Raynes Park announce the largest podded dwarf Pea ever produced, but as they are planting as large as possible an acreage for 1924, seed is not procurable this season. As far as pods and Peas go it is as near as possible a replica of the famous exhibition Pea Quite Content, but it only attains a height of 1½ft. to 2ft. As the illustration shows, it is very prolific. Messrs. Carters have a new French Bean, Carter's Sunrise, said to force as well as Ne Plus Ultra, but to be far more prolific. A new Runner Bean, White Monarch, is described as a white selection from Scarlet Emperor, equally prolific and handsome. A new Cucumber which is highly resistant to the dreaded black-spot is aptly called Constitution. It is a handsome fruit with a neat short neck.

CARTER'S GIANT PODDED DWARF PEA.

HARDY BORDER PINKS

New Varieties for this Season.

MR. JAMES DOUGLAS of Great Bookham, is sending out this season three excellent novelties all delightfully fragrant. Dainty Lass is deep rose pink with a crimson centre; Goodwood, a prettily fringed sort of soft shell pink colouring with a crimson centre; and Rosemary a dwarf, stiff habited variety, salmon-rose, centred deep carmine. These are all worthy additions to Mr. Douglas's already long list of sturdy, compact habited Border Pinks.

There is no need to enlarge on the beauty of Mr. C. H. Herbert's more or less Perpetual-flowering Pinks. They have often been recommended in THE GARDEN and most readers have, at any rate, some of the varieties in cultivation.

Mr. Herbert is sending out this season the finest batch he has yet submitted and that, everyone will agree, is a great deal. These are called Bridesmaid, Fire King, Lord Lambourne, Mrs. Giffard Woolley and Red Indian.

Bridesmaid is shell pink in colour with a rich salmon base. This colour is slightly suffused through the petals. It has stout stiff stems each bearing three or four flowers. Fire King is a very welcome new addition to these "Herbertii" Pinks. The flower stems are a foot or more long and are well carried and the plant is a good grower. Lord Lambourne probably considers himself honoured by the variety named after him, for its colouring is quite unique in Pink or Carnation. Very difficult to describe the raiser calls it "dark cerise with a darker red base." Mrs. Giffard Woolley is surely one of the largest and handsomest Pinks yet raised. It is of a delicate salmon shade with a deeper salmon base which throws up the exquisite form of the flower. This is a free and strong grower and when cut might easily be mistaken for a richly coloured Enchantress Carnation. Red Indian opens bright cherry red, but the expanded flowers the raiser describes as Indian red. They are, at any rate, rosy-crimson, with a maroon tone. This is a very free-flowering sort. The bases of the flower stems, after the flowers are cut often produce more flowers and "grass." Bridesmaid, Lord Lambourne and Red Indian have each received the coveted award of merit. It is fairly safe to prophesy that Fire King and Mrs. Giffard Woolley will receive the same distinction if and when submitted to the Floral Committee.

That the raisers of the splendidly floriferous Allwoodii have not been marking time their

novelties for 1923 conclusively demonstrate, for Messrs. Allwood's productions are rapidly becoming flowers of quality. Whereas the first varieties sent out produced good massed effect, and little else, the varieties now coming into commerce can be used in a dinner table decoration, for instance, including choice greenhouse flowers, without looking ill bred or out of place. The novelties are Alfred, pure white—this should entirely supersede Harold; Arthur, a greatly improved Ruby; Barbara, rich crimson, fully double; Dickon, bright centred dark maroon; Edith, white with a violet eye; Matty, semi-double, fringed reddish cerise, with

NEW PINK (HERBERTII) RED INDIAN.

maroon eye; Robin, double deep brick red; and Sybil, flesh pink, semi-double, with the smooth solid petal of a Carnation. Robin has a specially fine, erect and sturdy habit of growth.

Messrs. Maurice Prichard and Son of Christchurch have been working on entirely different lines from Mr. Herbert, Mr. Douglas or Messrs. Allwood. It is, indeed, singularly fortunate that four firms should simultaneously be working on this valuable plant from quite different angles. Some of the newest of Messrs. Prichard's varieties are mentioned below. Donnizetti is a splendid flat shapely single variety of vivid rosy-red colouring with a maroon eye. Gen. Freyburg, V.C., is a double variety with deep carmine flowers 3 ins. across. Magnificence is a fine double white with chocolate markings. Mozart is another vivid rosy-red single variety, small flowered, but very

free and lasting long in blossom. B. O. Prichard is a fine double rose self, and Ruy Blas a striking single red variety with a deeper eye.

The old florists who, a generation ago, worked so long and so hard to improve the markings of the laced and fancy Pinks, mostly of delicate constitution, would, indeed, open their eyes in wonder could they see the flowers we admire to-day.

THE ASTILBES

WHILE it requires a little stretch of the imagination to picture these plants as possible future rivals to such old border favourites as Delphiniums, Lupins, Phloxes, etc., they are unquestionably some of the finest summer and early autumn plants we have, and, unless I am quite mistaken, are becoming increasingly popular year by year, as their possibilities for the decoration of the flower garden are realised. Among other claims to recognition are two which stand out prominently, namely, their ease of culture and their gracefulness when in flower. Another, and perhaps hardly less worthy point, is the adaptability of the plants, both as regards soil and position, for although, like many other plants, they will, naturally, respond to a compost made to their liking, they will grow in any good garden soil.

Planting may be done at any time from autumn onwards, during favourable weather, until early spring, so that the present time is a suitable one for anyone wishing to commence their culture. In selecting a place for a group or bed of them other than the herbaceous quarters, an ideal spot may often be found by a pond or streamside, and it matters not in the least if a considerable amount of shade has to be reckoned with; indeed, such is advantageous if it is the midday sun which is shut off. Such a position as here suggested is nearly always a cool one for the roots of plants, and that is one thing above all others for which the Astilbes are grateful. I have heard the remark that the range of colour of these plants is too limited, but, personally, I cannot see why it should affect their popularity. I ask, Would the Delphinium occupy its proud place to-day had it given us a host of tones? Where it is necessary to have something in flower in the bed or border devoted to Astilbes early in the season, various bulbs may be used, or a groundwork of Polyanthas or Myosotis offers itself, and, should an additional display be required with the plumes of the Astilbes, some of the hardy Liliums are useful. When massed in a bold bed by waterside the various-toned Japanese Maples associate very pleasingly with them, so do a few plants of such a decorative Grass as Eulalia (Miscanthus) japonicus zebrina.

The following are all good sorts, and, when well grown, will add distinction to any suitable site. It should be borne in mind that the heights of the several varieties may vary considerably according to soil and season, but those given may be accepted as a fair guide.

	Feet.
Ceres, pink with lilac tone	2½-3
Brunhilde, cream pink	2-3
Gloria, rose toned pink	2-3
Kriemhilde, salmon pink	3
Princess Mary, rosy crimson	3
Pink Pearl, pale pink	2
Rutilans, rose carmine	3
Salmon Queen, salmon pink	3
Siegfried, rosy salmon	3

Of the taller-growing ones:

America, rosy mauve	4
Davidii, purplish	5
Grandis, white	5
Grandis rosea magnifica	5
Gruno, salmon pink	4
Sulland, reddish tone	5-6

HENRY TURNER.

CORRESPONDENCE

DOUBLE WALLFLOWERS.

REMARKING to a kindly Dutch hotel keeper that I was going on to Leeuwarden, he burst out, "Ah, Leeuwarden, I like Leeuwarden—my mother came from Leeuwarden," and my heart warmed to him at once. When I read Mr. Arnott's interesting notes on the above and his reference to the fact that they were only raised from cuttings, my heart again warmed, and I was carried back fifty years. After long years spent in business in a smoky Lancashire town, where not even grass could live, my mother, a townswoman, coming here, broken in health, plunged into all the delights of cottage gardening, striking cuttings, raising seeds, dividing all the old-fashioned things and so from childhood I have loved the plants kept for us by the mothers of the world, who, tired and sick of the troubles of life, have turned out into the garden for a change and forgot their troubles, or who, to retain some plant planted or cherished by a late mother, made a few cuttings or divided the old plant lest it also passed away. I retain an old Polyanthus, a relic, kept by continuous division, of a variety brought into this county by a young bride four generations ago—a piece of a mother's favourite—and kept in existence by her garden-loving descendants. The old double Wallflowers, therefore, appeal to me. I used to have a number of sorts, but am now down to the two double yellows mentioned and the old double red. I have now lost the old double black-red which used to be grown in the south-west under the appalling name of Bloody Warrior.—J. STORMONTH, *Kirkbride, Carlisle*.

SOME EARLY SPRING FLOWERS.

AMONG the earlier Snowdrops, *Galanthus byzantinus* was the first to shew flower here this season, from seeds kindly sent me several years ago by Mr. E. H. Woodall from Nice. It is a fine broad-leaved stately plant. *G. cilicicus* closely followed it, and then a beautiful early form of *G. Ikarie* which came to me from Mr. E. A. Bowles' garden. *G. Alleni*, from the same source, will not be out for another week or two. This is one of the finest and most vigorous of all here, and my stock of it, now quite an important one, emanated from the gift of one bulb. From seed of *G. Fosteri*, too, crossed with the pollen of *G. Whittallii*, is now flowering what is an obviously true hybrid between the two parents. Also in bloom are several selections of *G. Whittallii*, one with leaves nearly as broad as a Tulip, "spotted" here growing among others by that keen lover of Snowdrops and good friend of mine, the late Mr. F. W. Harvey, some time editor of *THE GARDEN*. *Eranthis hyemalis* (that little *hors d'œuvre* of the garden that whets one's appetite for the spring feast) has been out for a fortnight, *Iris Histrio* a week, and on trying for the first time, I find that *I. reticulata* will stand very gentle forcing, and it is in flower to-day (January 10) in pans, fragrant and delightful in the house.—F. HERBERT CHAPMAN, *Rye*.

MESEMBRYANTHEMUMS OUTDOORS.

I HAVE read the article signed "Z" in your issue of January 13, and I feel that I must answer the questions asked therein by him. My garden is in a very favoured situation near Plymouth, hanging over an estuary, and is certainly one of the favoured places. I am growing here most of the succulents, and I have quantities of the small *Mesembryanthemums* growing in the open, on some rocks; they seem to do perfectly, and

all varieties that I have tried (they are very many) succeed. I have also a large variety of Agaves, Aloes, Cotyledons, etc.

I quite agree with his praise of *Olearia semidentata*, and *O. chatanica* is nearly as beautiful. I have *Prostanthera rotundifolia*, but not violacea, as, so far, I have not been able to obtain it.

Again I have been following the same lines as "Z" in growing the "greenhouse"

because it and *Aristea fruticosa* differed from all the other known species in having a shrubby stem. The plant was of easy cultivation and never failed to flower every succeeding year. During the growing period it was kept warm, but cool and dry in winter.—HORTULANUS.

THE NICE SNOWFLAKE.

THIS pretty picture of a potful of the little-known *Leucojum nicaense* shews how amenable this bulb is to cold frame treatment. Mr. St. Quintin of Scampston Hall, Yorkshire,

received one bulb of this dainty plant that had been collected near Nice five years ago, and in that period it has increased to a potful. What it needs absolutely is a dry, warm rest during the summer. No water should be allowed to touch it during the months of July, August and September, but given that necessary dry rest there is no difficulty in its culture. Being quite hardy it needs no heat in winter but it does not like being drowned by constant rains, so that the shelter of a frame is desirable. Flowering in spring about the same time as the Vernal Gentian, I can imagine nothing prettier than the contrast these two gems make when shewn together. On the hills at the back of Nice, where it grows, it flowers the third week in April most abundantly, but the hot suns burn up the flower too quickly. Lucky for the plant! as, if it were in flower for any

LEUCOJUM NICAENSE AT SCAMPSTON HALL.

Rhododendrons—*Sesterianum*, Countess of Haddington, Lady A. Fitzwilliam, Dalhousie, Nuttallii, Lindleyanum, and many other of the tender ones—which have all flourished for several winters in the open, without any protection.

I shall be glad to shew my collection to "Z" if he should ever be down in this country, and to answer any questions that he may wish.—WILLIAM ARKWRIGHT, *Wembury, Plymouth*.

ARISTEA CORYMBOSA.

I WAS greatly interested in the note "A Quaint Iridaceous Plant," described on page 652 in your issue for December 23, 1922. This quaint and beautiful old-fashioned plant was well known to me when I commenced gardening. Although the pale blue flowers were rather fugitive individually, they were produced in succession over a considerable period on old plants. The latter had a clear stem rising from the pot, branching on the top and forming a very bushy low standard, densely covered with short light green leaves. At the time I speak of it was known as *Witsenia corymbosa*, the name given to it by Ker in the "Botanical Magazine," t. 895. It was also figured in "Lodig's Botanical Cabinet," t. 254. Several names have been given to it by different authors, and the late Mr. J. G. Baker named it *Nivenia corymbosa*,

length of time, it would long ago have been gathered or dug up!—E. H. WOODALL.

SHRUBS FOR TOWN GARDENS.

IT is interesting to read in *THE GARDEN* from time to time of shrubs that flower at Aldenham House, Munstead Wood, and at other gardens in the South of England. How we Northern shrub lovers envy the atmosphere and climatic conditions which would enable us to provide such displays. For some time my tent has been pitched in a large Yorkshire city where injurious fumes always contaminate the atmosphere, so that the balance is heavily weighted against healthy vegetation. Yet in spite of this there are many enthusiastic gardeners here, men and women. Almost every resident in the suburbs is anxious that his garden shall be at once a credit and an inspiration. Having proved the value of certain beautiful hardy flowering shrubs for town gardens, I thought my experience might be of interest to readers of *THE GARDEN* who dwell in similar situations. One of the earliest plants to flower is the lovely yellow Jasmine, *Jasminum nudiflorum*. The bright yellow blossoms open in January or February, and at that dark season afford the greatest pleasure. I find that any ordinary soil will yield adequate sustenance,

and that the best position in which to plant is at the base of a south or west wall. The shrub which blooms next in order of time is *Rhododendron præcox*. This delightful kind should be in every town garden. My bushes are a yard high, and to preserve the delicate pink hue of their flowers I have planted them among some well branched specimens of *Prunus pissardi*. When planting *Rhododendron præcox* it is beneficial to incorporate a good dressing of leaf-mould with the soil. The genus *Ribes* is the next to provide a doral feast. It would appear that our "coal-measures" soil is conducive to the formation in this genus of vigorous and floriferous growth. The bushes provide a picture of perfect health, and they never fail to bloom. The only attention I ever give is to remove old and weak shoots immediately after flowering. I have three sorts in my collection, and all of them bloom in April and May. The red (*R. sanguineum*) is the most suitable because its flowers do not reveal the presence of soot so readily as the white variety (*R. sanguineum album*) or the yellow species (*R. aureum*). Several of the Barberries (*Berberis* species) succeed here, and they open at the end of May or early June. I should give the palm to *B. stenophylla*, for, in my judgment, the garden is never more beautiful than when the pendulous branches of this gorgeous shrub are densely hung with bright yellow flowers. *Darwinii* and *vulgaris* both justify their place in a northern collection. I never prune the shrubs save to remove dead wood, and they grow in ordinary soil. Perhaps the most popular and universal shrub here is the Lilac. It is to be found in practically every garden, and makes a brave show in early June. In my own collection I have, in addition to the type (*Syringa vulgaris*), *Mme. Lemoine* (double white) and *Souvenir de L. Spath* (deep purplish red). Of the two latter I would speak in terms of highest praise. To attain the best results Lilacs must be grown in good soil and have the

benefit of full exposure to sunlight.—Geo. H. COPLEY, *Leeds*.

A BEAUTIFUL PRIMULA.

I ENCLOSE a photograph of *Primula sphærocephala*, taken on September 29 last year, which might interest your readers. The plant bloomed well on into October till spoiled by the frost. The seeds were sown in March last in pans and pricked out later in a damp, shady spot. They should be treated as biennials, but mine look like flowering again this year.—M. J. WOLFLEY.

[*P. sphærocephala* is a violet coloured species, hailing from China, but obviously closely related to the beautiful *P. Mooreana* and others of the "capitata" kin.—ED.]

FERN SPORES IN GARDEN SOIL.

I WONDER how many readers of THE GARDEN

have seen Ferns growing inside bottles thrust into the ground upside down. In a cottage garden here are some sixty "Camp Coffee" bottles used as edging to a path, and most of them have Ferns growing from the soil forced up into the neck of the bottle. The owner tells me the bottles have been there about five or six years, and probably the Ferns are now at their best. I was allowed to remove four bottles to be photographed and enclose a print. The Fern in the bottle on the left is the common Ribbon Fern, *Pteris serrulata*, and the others appear to be the Soft Shield Fern. I imagine that pot Ferns have been stood on the spot in the summer and shed their spores, but it must have been a long time ago, as the present occupier has been in the cottage for a good many years and says they have never stood Ferns there. I have read that this may be expected to happen anywhere if a glass jar is inverted in the soil, but have never before seen it.—H. C. WOOD, *Lingfield*.

"CODDLING" ALPINES.

AN article entitled "The Coddling of Alpines—a Warning to Rock Gardeners," appeared recently in the *Times*. The writer—presumably an expert—condemns in no measured terms the use of glass protection for the more delicate kinds.

I am far from being an expert rock gardener, but I certainly am an enthusiast, and this article has caused me a certain amount of bewilderment as, apart from the almost universal recommendation of the practice by all writers, my own limited experience has found it most valuable. I have certainly found none of the spotty appearance attributed by the writer to the use of these "silly sanatoria." On the contrary, to take one instance

A COLONY OF PRIMULA SPHÆROCEPHALA.

only, those of my *Kabschia Saxifrages* which I have thus protected are not only vividly healthy, but shew great promise of bloom, while those not so sheltered look far from happy after the drenching rains of the last few weeks.

I venture to encroach on your good nature with this somewhat lengthy epistle as I think the subject might be of interest to many of your readers, and your views would certainly be most welcome to a tyro like myself.—COTSWOLD.

[Most readers would probably agree that the building of "sanatoria" in the rock garden should be kept to a minimum, but undoubtedly a certain amount of protection is necessary for woolly foliaged plants, such as many *Androsaces*, at any rate in the neighbourhood of manufacturing areas. From a cultural point of view there is no possible objection to such "sanatoria" since most alpines do splendidly under glass in winter and early spring, but few people like their rock gardens to look like the Mappin Terraces at the Zoological Gardens or worse!—ED.]

LITHOSPERMUM ROSMARINFOLIUM.

THE winter so far being mild, we have enjoyed an unusually good shew of blossom on this gorgeous species, whose deep azure flowers seem to be stained with the magic colour of its own native home of Capri. Given a sheltered, sunny position, *L. rosmarinifolium* will stand considerable frost with impunity, and although some have difficulty in satisfying it, the plant grows away here with the vigour of a prostrate Lavender, to which, in foliage and habit, it bears no little resemblance. It likes best a free, even stony, root-run, such as the top of a low retaining wall might afford, and a few lumps of old mortar are appreciated. The flowering season varies a good deal in open-ground plants, this being governed by the weather to great extent. As a rule, however, we expect the first blooms to open in late autumn, and a succession is usually maintained (omitting severe spells) until February or later. This is a first-rate cold-house plant. Propagation is very easily effected by cuttings struck about midsummer.—N. WALES.

THE FERNS IN THEIR STRANGE "CLOCHES."

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

General Work.—In the ordinary course of events we may expect better weather and a gradual return to brighter and longer days, so it is essential for us to push on with the preparation of all vacant ground for future crops. Weeds are beginning to push up, and, where possible, they should be dug into the soil and on no account be allowed to produce flowers. Pea sticks can be prepared, and "seed" Potatoes for the main crop spread over the floor of a cool shed, where they will form short-jointed growths, and on wet days the ware or kitchen Potatoes can be looked over for diseased tubers, while other vegetables in store may also be examined.

The Flower Garden.

Climbing Plants.—In many gardens climbing plants are quite a feature and although often it is a good plan to allow them to grow unchecked, specimens on or near the dwelling-house will need attention. Wistarias and such like should be overhauled and any weak growths removed. Where a climber is intended to cover a certain area, a few young shoots should be retained near the base whenever possible, eventually to take the place of any worn out branches or dead wood. Here at Castleford, trees of useless varieties of Apples and Pears have been employed for supports of the various forms of Vitis, Lonicera and Clematis, especially those of the montana type. The climbers have in most instances covered the trees, and one can now see the plants at their best. Solanum crispum, S. jasminoides and Polygonum baldschuanicum, are also suitable for this purpose. When planting climbers at the base of useless trees, a portion of the soil should be taken out and replaced with a mixture of loam and leaf-mould or good garden earth.

Rambler Roses.—Roses of the Dorothy Perkins type should now be overhauled if the work was not done immediately after the flowering season, cutting out the old wood and tying in the growths produced last summer. Replace decayed poles or arches and use good quality tarred twine. These remarks are important because it is nothing short of a calamity when poles and twine give way just as the plants are in bloom. Old and worn out specimen plants should be replaced as the work proceeds, and I can strongly recommend Scarlet Climber; it is one of the finest Pillar Roses in commerce.

Fruit Under Glass.

The Orchard House.—This structure generally accommodates fruit trees growing in pots, perhaps in addition to a few permanent trees such as Peaches and Nectarines growing on the sides of the house. The latter should be pruned and cleansed and the trees in pots should also be dealt with in like manner. The pruning of all trees should now be completed. With pot trees it is a great mistake to overcrowd the shoots or to leave the growths of Peaches too long unless they are needed for the extension of the tree. As a rule each growth can be cut back to within 6ins. of its base but always prune to a leaf bud. Cherries, Plums and Figs are often grown in pots, also a few Apples. The pots should be plunged nearly to the rims and the roots must always be kept well supplied with water. Admit air freely.

The Hardy Fruit Garden.

Small Bush Fruits.—The pruning of these trees should now be finished and when the operation is completed lightly fork over the ground and give a mulching of manure. Red and White Currants should be pruned on the spur system, cutting back the side shoots to two or three buds, and allowing the leading growths 6ins. or 8ins. extension. Branches occasionally decay, and where this has happened a new shoot should be retained to take its place. The pruning of Black Currants consists of thinning out the old wood, leaving the strong young growth of last season. Old neglected trees may be rejuvenated by cutting all the branches near the ground level. New shoots will spring up from the base and form the fruiting wood next year. Gooseberries should be well thinned to allow light and air to enter the centre of the bushes and also to permit the fruit to be gathered with ease. If possible the Gooseberry should be grown on a single stem about 8ins. in length, and, when pruning, low-lying branches must be removed in their entirety.

T. W. BRISCOL

(Gardener to W. R. Lysaght, Esq.
Castleford, Chepstow, Gloucestershire.)

FOR NORTHERN GARDENS.

The Kitchen Garden.

Leeks require a long period of growth for their full development, so the seed should be sown as soon as weather conditions will permit. Sow in a sheltered corner in rich soil, either broadcast or in lines 6ins. apart; as the crop will be planted out later on, the seed bed need not occupy much space.

Brussels Sprouts.—When these are sown in autumn they turn in rather early for general purposes, and when sown out of doors in spring they often fail to attain full size. It is advisable therefore to sow in boxes in a cool house, the seedlings to be in due course pricked out into a cold frame. Solidity is one of the best varieties.

Kidney Beans.—Where these are required early a sowing should be made in a warm house in 9in. or 10in. pots, placing four or five seeds in a pot. Use a fairly rich soil and leave room in the pots for an inch or so of top-dressing later on. Use a dwarf variety such as Ne Plus Ultra.

The Hardy Fruit Garden.

Planting.—If the planting of fruit trees or bushes was not undertaken in the autumn, the work should be done now, whenever climatic conditions will permit. Examine the roots and cut away any parts that are damaged or diseased and shorten any bare roots of undue length. See that the bottom of the pit is level or slightly convex rather than concave, spread out the roots and tread the soil firm as the filling-in of the pit proceeds. Beware of planting too deeply; the aim should be to keep the roots near the surface. Fruit trees in the open should be staked promptly and wall trees should be nailed into position.

Transplanting Young Bushes.—Where cuttings of Gooseberries or Currants were inserted two years ago these should now carefully be lifted and transplanted into nursery lines about 2ft. apart, allowing 18ins. between the plants in the line.

The Flower Garden.

Sweet Peas.—The seeds should be sown during the course of the week. Some cultivators sow in small pots, but excellent results are obtained by sowing in ordinary propagating boxes. Maiden loam with a little old hot-bed manure forms an excellent compost; pass the whole through a 4in. sieve and place the rough portion in the bottom of the boxes. Sow in lines 2ins. apart allowing an inch between each seed in the lines; drop the seeds into holes barely 3in. deep formed by the aid of the forefinger or a blunt wooden peg. Place the boxes in a moderately warm house till germination takes place. The utility of chipping the seeds is a debatable subject. I never practise it and have had no cause to complain of results. The purple and lavender shades germinate least satisfactorily on the whole.

East Lothian Stocks.—If not already done, seed of these useful plants should be sown without delay. Ageratum and Lobelia may also be raised from seed now. An intermediate temperature is suitable for germinating all the foregoing. Cover the boxes with sheets of glass or with newspapers to prevent too rapid evaporation.

Fruit Under Glass.

Early Vines which have made about a foot of growth should have the shoots only slightly tied down at first as they are very easily broken or heeled off. The afternoon of a sunny day is the best time for undertaking this work as the shoots are then in a more or less flaccid condition.

Late Vines which should now be started should have a temperature of 45° at night, with a rise of from 5° to 10° during the day, the latter figure being for a spell of sunshine. Spray the rods gently with lukewarm water morning and afternoon.

Cucumbers.—If a sowing is made now the subsequent plants will begin to bear early in summer. Sow singly in 3in. pots only partially filled with fairly rich soil and plunge in bottom heat. A minimum temperature of 60° will suffice. Lockie's Perfection is an excellent variety.

The Shrubby.

Planting.—Advantage should be taken of open weather to carry through this operation. In addition to dwarf shrubs, such as Hypericum and Ericas the front of the border or bed may be furnished with such plants as Funkias, Hellebores and Saxifraga peltata.

CHAS. COMFORT.

(Formerly Head Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Calceolarias of the large-flowered herbaceous section sown last August should now be ready for potting on. The plants enjoy a rich compost, to which some dried cow-manure or old mushroom bed manure should be added. After potting, the plants should be kept close for a few days until the roots get a hold of the new compost. Afterwards they should be kept as cool as possible, with ample ventilation according to the weather conditions. These plants are very subject to attack by green fly, but this pest may be prevented by frequent fumigation. Calceolarias of the shrubby section, as represented by C. Clibrani and C. Allardii, propagated by cuttings last autumn, should now be potted on. These plants can do with a slightly heavier compost and firmer potting than the herbaceous section.

Calceolaria integrifolia (syn. C. rugosa) is an old garden plant which is worthy of more general cultivation for the conservatory, as it will make a fine large specimen if potted on into 8in. or 10in. pots. It also makes a fine specimen if planted out in a bed or border in an unheated house. This species is hardy outdoors in South Devon and Cornwall. Plants propagated from cuttings last season should now get a shift into large pots, and are best grown in a perfectly cool house.

Calceolaria Burbidgei is a fine kind for autumn and winter flowering. Plants rooted from cuttings next month will make good plants for the stages if stopped several times and grown on into 7in. pots. Last year's plants if potted on into 10in. pots will make large specimens 6ft. or 7ft. high.

Erica melanthera has now been in flower for several weeks. This South African species is one of the largest growing and easiest of our greenhouse Heaths, for if potted on into 10in. pots it soon makes large specimens from 4ft. to 6ft. high. On the other hand, it can be grown and flowered with wonderful freedom in 5in. pots. It is one of the easiest of greenhouse Ericas to propagate from half-ripened twiggy growths. These should be about 2ins. in length and inserted in pots of fine sandy peat. The cutting pots should be half filled with crocks and the compost rammed very firm, covering the top of the compost with clean sharp silver sand. The cuttings should be well watered in with a fine-rosed watering can, and when the pots have drained they should be stood under bell-glasses in a cool house. The cuttings root more quickly if they are stood in a case with slight bottom-heat, but the house otherwise cool. All the soft-wooded winter-flowering Ericas may be propagated in this way at this season or as soon as suitable cuttings can be obtained.

Sweet Peas sown in pots last autumn and wintered in cold frames should now be ready for transferring to their flowering pots, which may be 8in. or 10in. in size. The compost should consist of good mellow loam pulled up roughly, with the addition of some old mushroom-bed manure, also some soot and a 6in. potful of fine bone-meal to every bushel of soil. The plants should be potted fairly firm and almost needless to say, in giving such a large shift—usually from 5in. pots—watering must be very carefully done until the new compost is well filled with roots. When well rooted and growing freely these plants enjoy plenty of water, and may be fed twice a week with diluted liquid manure and soot-water, giving guano occasionally for a change. The plants must have a cool, airy house and be given plenty of air without draughts on all favourable occasions. They should as they require it be kept secured to neat supports.

Tuberous-rooted Begonias.—If not already done, seed should be sown, watering the seed pots or pans and allowing them to drain for several hours before sowing. The dust-like seeds should be sown on the surface of the soil. If the seed-pans are covered with a piece of glass, they will not require any watering until the seeds have germinated. If the plants are well grown, the strongest of them should flower well during the autumn and make a good succession to the plants grown from dry tubers. After selecting what is required for growing on in pots, the rest of the seedlings, after being hardened off, should be planted out during June, when they will make good tubers for next year. A batch of dry tubers may now be selected and started into growth in a warm house, laying them out in shallow boxes with leaf-soil and sand, or they may be put directly into small pots, watering them carefully until they start into growth.

J. COURTS.

Royal Botanic Gardens, Kew.

NOW is the time to make enquiries for Spring Planting of

MERRYWEATHER'S FRUIT TREES

THE DAMSON

FOR PROFIT IS THE

"MERRYWEATHER."

DAMSON - MERRYWEATHER.—(F.C.C., R.H.S., 1913). This has caused quite a revolution in Damson growing, the growth is very similar, and as vigorous as Victoria Plum. Unlike all other Damsons it commences to fruit as soon as the tree is two or three years old. The fruit is the most wonderful feature, on account of its enormous size. They could readily be mistaken for a late Plum, until tasted, when, although the size is so much above that of the largest Damson grown, the true flavour of the Damson is retained. We believe there is a large future for this introduction, and, like Bramley's Seedling amongst the Apples and Victoria amongst the Plums, MUST be in every orchard or fruit garden in the country.

PRICE:

Maidens, 2 6 each. Bushes and Pyramids, 3 -, 4 -, and 5 - each. Half Standards, 4 -, 5 - and 7 6 each. Standards, 5 6, 6 -, 7 - and 10 6 each. Dwarf Fan Trained, 6 -, 7 6 and 10 6 each. Espalier Horizontal Trained, 3 tiers, 7 6, 4 and 5 tiers, 10 6 each. Single Cordons, upright, 3 6, 5 - and 7 6 each, an ideal Cordon fruit.

Fruit growers should not miss planting

CURRENT SOUTHWELL RED

It flowers very late, and so escapes late frosts. Long bunches of bright shining red berries are formed, the individual berries being very large and uniform in size. When gathered it has a very fine appearance and commands the top price in the market.

Price 8d. each; 7/- per doz. Extra strong, 1 - each; 10 - per doz.

ENGLISH NICOTINE.

NICOTINE INSECTICIDES are by far the most efficient for destroying insects infesting plants and fruit trees, and perfect culture cannot be attained without the judicious use of Nicotine. Be sure the Nicotine Insecticide employed is Campbell's, made in their own English works, and guaranteed purest and best.

CAMPBELL'S ENGLISH NICOTINE, 95-98 per cent. guaranteed, price on application.
CAMPBELL'S NICO SOAP (Nicotine Soap). The best Potash Soft Soap, plus $7\frac{1}{2}$ per cent. Nicotine, unrivalled for syringing or spraying. Prices— $\frac{1}{2}$ lb., 2/-; 1 lb., 4/-; 10 lb., 32/-

CAMPBELL'S NICOTINE VAPORISING COMPOUND. Nicotine content, 50 per cent. Prices—10z., 16/-; 40z., 39/-; 80z., 76/-; $\frac{1}{2}$ pint, 9/-; 1 pint, 17/6; $\frac{1}{2}$ gallon, 61/-.

CAMPBELL'S NICOTINE FUMIGATING ROLLS, very simple and effective. In four sizes, for 500, 1,000, 2,000 and 3,000 cubic feet. Prices—7d., 10d., 1/6 and 2/- each.

CAMPBELL'S PATENT SULPHUR VAPORISER. The best method of exterminating Mildew from plants in glasshouses. In two sizes, for 5,000 and 10,000 cubic feet. Prices—18/- and 20/- each.

CAMPBELL'S CAUSTIC ALKALI for the winter washing of dormant in and outdoor fruit trees. Prices—1 lb., 1/-; 5 lb., 4/-; 10 lb., 7/6.

CAMPBELL'S LEMON OIL and WEEDKILLER, prices and particulars on application.

VEGETABLES ALL THE YEAR ROUND

THE present month must undoubtedly be regarded as one of the most important in the year by those who aspire to the production of an unbroken succession of excellent vegetables, and this notwithstanding the fact that far more seeds will be sown in March than can safely be consigned to earth until February has run its course. At the moment we have not to consider only the work that is to come, but the work that is past since it is now that we shall see the fruits of it.

A NOTE ABOUT SOILS.

It is notoriously a period of treacherous weather and the man who would achieve the finest results must be ready to grasp each golden moment as it reaches him, for it can never come again. The strong land which was deeply, thoroughly and roughly dug in the autumn or early winter, and manured at the same time, will go down splendidly in favourable weather under the influence of the fork and we shall soon have a capital tilth, congenial alike to seeds and plants. Grasp the first chance then to dig it over, but make no efforts in that direction when the land is sodden, or infinitely more harm than good will be done.

Soils which have been allowed, wisely or unwisely as the case may be, to lie solid through the winter, should be dug and manured as soon as possible, and here again it is essential that the weather shall be accepted as the governing factor. Bear in mind that it is impossible to work too deeply, that the manuring must be on the generous side, preferably with thoroughly rotted cow manure on sandy lands if it is procurable, and that there must be consolidation, either naturally by settlement or artificially by heavy treading, before the prospects can be regarded as even reasonably good. Seeds do not germinate and grow vigorously, young plants do not take kindly to a loose medium and there is the further supreme disability that looseness directly favours dryness, which is a condition of affairs that is by no means conducive to the best results. In all soils and for all crops firmness is necessary, and in light, sandy lands it must be looked upon as of paramount importance. If natural settlement is to be relied upon at least a month must elapse between cultivating and sowing or planting; as a matter of fact treading is much wiser and it ought to be done heavily on each spit and not simply on the top, because this latter will not be fully effective.

CROPS IN GROWTH.

Speaking generally, the several green crops look well and, unless something over which growers have no practical control occurs, the supply should last easily until Spring Cabbages come in. A word or two about the last named. It is comparatively common for them to reach a standstill that is almost complete in the winter and it often requires a little special persuasion to set them going again. For this purpose nitrate of soda is unequalled, but it should not be used at more than one ounce to the square yard, and usually three-quarters of an ounce will suffice, and in most soils it is not desirable that it shall be used until nearly the end of the month. Young plants which have spent the winter in nursery beds should be set out in permanent positions on the first favourable opportunity. Dead and yellow leaves should be removed from all green vegetables as necessary; they are unsightly and valueless.

SEEDS TO SOW.

The soil and climate of the garden must have scrupulously careful consideration when this particular work is in hand, but a big start will be made in all instances. Where either a gently

heated frame or greenhouse is at command it is certain that there will be sowings, small or large, according to individual circumstances and requirements, of Brussels Sprouts and Cauliflowers, with Leeks and Celery in many places and Onions certainly, where the cultivator desires to produce three or four pounders—the chances are against success, but we all like to try our 'prentice hands. Shallow boxes and a light compost will suit all except the Onions, which are better in a box 8ins. or 10ins. deep and a richer soil. In all instances the soil must be firm and pleasantly moist and the seeding thin, at once to economise in seeds and in labour when thinning. A high temperature is prejudicial rather than favourable, but it is undesirable that the fall shall be lower than to 38° at night.

It is when we turn to outdoor operations that we have most closely and intelligently to consider our climate and surroundings. Those who enjoy the possession of a border with a south aspect and of which the soil is comfortably on the light side can go ahead, but the man who has no such genial site and whose soil is naturally cold and heavy must walk very warily or his failures will be out of all proportion to his successes. Parsnips should be sown in all instances where it is possible to get on the ground. Drop clusters of seeds 12ins. apart in lines 15ins. to 18ins. asunder. At least a couple of rows of early Peas must go in somehow, even at substantial risk; set the seeds rather closer than would be necessary after the middle of March on a flat, firm base and cover in 3ins.; the distance from row to row should be equal to, or slightly more than the height of the variety. Long-pod Beans, too, are a necessity and the same rules in respect of sowing and distance should be observed as for Peas. If circumstances permit of a sowing of each of these early in the month there should be a second at the end to maintain successions.

Admirably sprouted sets of a first early Potato ought to be planted; the distance between the lines must depend on the habit of the variety chosen, but in all cases the covering should be from 4ins. to 6ins. according to the staple. It is certain that both Turnips and Spinach will be sown in numerous gardens, but they have not the outstanding importance of the kinds previously named.

Finally, we may speak briefly of Onions. If the foundations of the bed were laid in the autumn, and it is feasible to get on the ground, by all means sow before the end of the month 3in. to 1in. deep in drills 10ins. to 1ft. asunder, but if the bed has had to be made since the turn of the year, sowing will have to wait until March unless the conditions have been peculiarly favourable to consolidation, since it is quite useless to attempt to grow this vastly important crop on any other than a solid bed.

W. H. LODGE.

FORTHCOMING EVENTS.

February 5.—National Chrysanthemum Society's Annual Meeting to be held at the R.H.S. Hall at 6.30 p.m. Lecture at the University College, Gower Street, London, W.C.1, at 5 p.m., by Sir John Russell, F.R.S., on "Development of the Idea of Soil Population." Admission free.

February 6.—Royal Caledonian Horticultural Society's Meeting.

February 7.—Lewes Horticultural Society's Annual Meeting. Lecture at the University College, London, W.C.1, at 3 p.m., by Mr. H. C. Thornton, B.A., on "Occurrence of Bacteria in Soil—Activities Connected with the Acquisition of Energy."

February 8.—Royal Gardeners' Orphan Fund Annual Meeting and Election at Simpson's Restaurant, Strand, London, W.C.2.

BOOKS

Willing's Press Guide.*—This useful Press directory with its familiar red and blue covers has just made its annual reappearance. This is the fiftieth year of publication. Besides English newspapers and periodicals, the titles, addresses and days of publication of the principal American, Colonial and Continental publications are included.

The Horticultural Directory.†—The new edition of this publication will be welcomed by amateur and professional alike. It contains a budget of information which will prove of inestimable value to all those connected with the horticultural world. Here will be found, indexed under their respective counties, all the principal private gardens in the British Isles, their owners and head-gardeners, together with full postal addresses. The names and addresses of all the leading nurserymen, seedsmen and sundriesmen are also given; so are horticultural societies, with their secretaries' names and addresses. Parks and public gardens have not been forgotten, and botanic gardens and experimental gardens in the Colonies have also been embodied in this very useful work of reference.

The Welsh Poppy.—A charming and elegant plant in its right place, beautiful in the fresh green of its pretty foliage and large, lemon-yellow flowers. *Meconopsis cambrica* is, or can be, a terrible pest where it is not wanted. In the rock garden or steps its habit of seeding into every available crevice and into the midst of every neighbouring plant is a pernicious one, and not a few who have established it in such places have repented grievously and wished that its thongy roots were more easily destroyed. Yet in the woodland this is often a most desirable plant. It associates well with native Ferns, creeping Ivy and such vegetation, and is quite content without sun. The single orange form is happily much less rampant, a lovely thing with all the good points of the type and few, or none, of the bad ones. Even less ambitious, if also, perhaps, less beautiful, are the double yellow and double orange. The latter is the more pleasing of the two, but both of them seem to lack the peculiar charm of the singles. *M. cambrica* is a true perennial in all varieties, but the double ones are often short lived.

A Novel Competition.—Mr. T. W. Sanders has, it is announced, undertaken to judge the entries for Messrs. Carter Page's Bean Competition. This competition should have considerable success, since everyone can and does grow Runner Beans, and the fact that there is no entrance fee or restrictions of any kind makes it an attractive way of increasing interest in the kitchen garden. All one has to do, it appears, is to buy a packet of Carter Page's well known Best of All and send in, next September, twelve Beans to compete for the prizes. The first prize is £25, the second £10, and there are fifty other prizes. Full particulars and rules can be had at the showrooms at 52 and 53, London Wall, E.C.2.

† "The Gardeners' Chronicle Horticultural Directory and Year Book for 1923." Published by the *Gardeners' Chronicle*, Limited, 5, Tavistock Street, Covent Garden, W.C.2.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

NARCISSI FOR MARKET (N. L. B.).—The most serviceable varieties of Narcissi for our correspondent to grow would, in the circumstances, be the following: Paper White, pure white; Princeps, sulphur white; Yellow Trumpet; Cervantes, very early, primrose yellow; Golden Spar, yellow self; Sir Watkin, primrose, rich golden cup; Emperor, perianth pale yellow, trumpet pure golden yellow; Potions ornatus, white with orange-red eye. These should be planted in large numbers rather than a few of many more varieties. Rabbits should be shot, of course, but to make sure of protection the half quarter should be adequately fenced in with small-meshed wire netting.

LAWN UNSATISFACTORY (R. H. B. Redruth).—As moss now covers the lawn it is evident that the soil is both sour and poor. Our correspondent does not say when the grass seed was sown—in spring or autumn—the former time we presume, and if the soil was too loose then and also poor and sour, the moss would spread at the expense of the grass roots as autumn weather came, last season being favourable for this condition to obtain. Thoroughly rake off as much moss as possible now and apply a good surface dressing of wood-ashes and, in addition, two barrow-loads of good loam, broken up or passed through a lin. mesh sieve, per square rod. Roll frequently while dry and next March sow more grass seed containing a fair quantity of Hard Fescue. Apply 2oz. per square yard finely ground bone-meal late in May.

ABOUT PLANTING SWEET PEAS (A. O. P.).—In the first place our correspondent should replace 2ins. or 1ft. of soil in the 3ft. trench without adding any manure to it. The remaining soil should have some well rotted manure mixed with it as it is returned to the trench. With the top layer, about 1ft. deep, mix 3oz. of bone-meal per yard run of trench, also some old lime rubble with the whole of the returned soil. About three weeks before the Sweet Peas are planted fork in lightly 2oz. of superphosphate of lime per yard run of trench. The work of filling should be done at once if the soil is dry enough, as it must not be disturbed while in a wet condition, then the whole will set down firmly—an important matter by planting time—the first week in April.

HARDY PLANTS FOR TWO LONG BORDERS (F. H. R. France).—As the borders are narrow, tall-growing plants would not be suitable, neither would it be very satisfactory to attempt the arrangement of tall, medium and dwarf-growing kinds in the usual way. An edging of blue or white Violas, or both, would yield a mass of bloom and also the following over a long period: Centaurea montana, Scabiosa caucasica, Anemone appendiculata, Achillea millefolium, Pinks, Delphinium spectabile, Pyrethrum in variety, Aubrietia Leitchii, Lychnis viscaria, Gaillardia, Poppies, Lobelia cardinalis, Hebe sanguinea, Coreopsis, Doronicum, Anthemis, Genui, Monarda, Alyssum saxatile, dwarf Michaelmas Daisies, Iris, Delphiniums, dwarf Phlox and Campanulas. These will provide blue, white, pink, rose, crimson, yellow, lilac, orange and purple colours.

FINE VARIETIES OF IRIS (A. E. B. Birmingham).—In a recent catalogue of Messrs. R. W. Wallace and Co., The Old Nurseries, Tunbridge Wells, most of all our correspondent's varieties are listed, including Asyrie, Ma Mie, Minc, Chereau and Mrs. Routh, all belonging to the Iris plicata section (aphylla of gardens). They also list Thorbecke. The types described as "Standard and falls copper and lavender, through yellow and brown," must refer to the Squalens or Variegata section, and of these we would prefer the latter section, in which the colours are brighter and better defined. An old one of this type is Graebius, with primrose standards and fall-veined and shaded purple. Prospero was new a little over two years ago and has pale lavender standard and deep red purple falls with paper margins. Others are Iris King, Maori King and Robert Burns. The last named and all the others except Prospero, perhaps, can also be obtained from Messrs. Barr and Sons, King Street, Covent Garden, London. The six can be selected from the above ten, for they are all good.

UNSATISFACTORY BORDER (M. E. Cheshire).—The soil is poor, as our correspondent says. About three parts of it consists of fine sand, with some small stones in it. The small creatures described are most likely springtails, which may feed on decayed roots, but they are not credited with eating and killing plants. They are often present in similarly sheltered places, even among window plants and in hot-houses. They must such places, simply for the sake of shelter. The Privet hedge and the eastern aspect are the chief sources of trouble. It is a question of light chiefly. The trenching and manuring will improve the soil. The lime may have deteriorated by becoming air-slaked, but it will be less carbonic and not waste the vegetable matter in the soil so much. The hedge should be kept down to a height of 4ft. and pruned twice a year. Delphiniums and Lupinus should succeed because they are tall, and Campanulas succeed in shade; but Antirrhinum and Nepeta require longer sunshine than the morning sun can give them to flower well, and they should be planted furthest away from the hedge. About 4oz. of lime to the square yard will be enough for a sandy soil. It will sweeten the soil and drive away or kill springtails and similar creatures. They had crept up and disappeared from the soil sent.

THE CAPE GOOSEBERRY (South Devon).—Seeds of the Cape Gooseberry (Physalis peruviana) may be obtained from Messrs. Sutton and Sons, Reading, or from Messrs. Ryder, Limited, St. Albans, who catalogue it under its synonym P. edulis. While it is not hardy in this country, there are no difficulties attendant on its cultivation, and we have seen it fruiting abundantly in

North Cornwall. The method followed was to sow seeds in gentle heat towards the end of February. Pick off the seedlings in small pots of leafy, sandy soil, keeping the seedlings as cool as possible till the beginning of May, when they were planted out of doors in an open, sunny position, allowing a space of 3ft. from plant to plant. No thinning of the shoots was practised, but the plants were allowed to grow naturally. In this way they fruited freely until the late autumn frosts killed the plants.

TREES AND SHRUBS.

FLOWERING SHRUBS FOR NORTH-EAST FRONT (E. Sutcliffe).—Forsythia spectabilis, Philadelphus Lemoinei erectus, P. microphyllus, P. Virginian, Hypericum calycinum, Kerria japonica fl. pl., Hydrangea arborescens grandiflora, Diervilla Eva Rathke, Colutea arborescens, Buddleia variabilis, Cytisus scoparius, Potentilla fruticosa, Spiraea Menziesii and var. triumphans, S. japonica and var. Anthony Waterer, Both Jasminum nudiflorum and J. officinale would be suitable for the porch. Being difficult to root from cuttings, Rosa Meysei is bidden; the alternative method of propagation is by layering. In raising from seeds few of the seedlings produce the wonderful lurid dark red flowers.

SHRUBS FOR BANK TO HIDE WALL (W. M. Cheltenham).—Back row: Berberis stenophylla, B. Darwinii, Cistus laurifolius, Escallonia langleyensis and E. Philippiana. For the front, plant Berberis Aquifolium, Hypericum calycinum, Olearia Haastii, Veronica Traversii, Clem. europaea fl. pl. (Double Gorse), with, possibly, Lavender and Rosemary.

CLIMBING PLANTS FOR WALL (E. A. G. M. Bucks).—South: Clematis dentata, C. rigidus, C. thyrsiflorus, C. Veitchianus, Escallonia macrantha, E. rubra and Ribes speciosum. North: Rose Gloire de Dijon, Hydrangea scandens, Jasminum nudiflorum and Clematis Jackmanni. West: Clematis Nellie Moser, C. Henryi, C. Lady Northcliffe, Choisya ternata, Cydonia japonica, Forsythia suspensa, Chimonanthus fragrans and Lonicera Early Dutch. East: Jasminum officinale, Pyracantha Lalondei, Lonicera Late Dutch and Trachelospermum japonicum.

FLOWERING TREES (W. E. W.).—The following trees should thrive in our correspondent's clay soil: Esculus Hippocastanum, A. carnea, Catalpa bignonioides, Crataegus Carnei, C. cordata, C. Crus-galli, Laburnum alpinum, Prunus Avium fl. pl., P. Padus fl. pl., Pyrus Aucuparia, P. baccata or spectabilis and Robinia Pseud-acacia. If our correspondent does not object to a number of Thorns (Crataegus), which are particularly hardy trees, include Paul's Double Scabrid.

SEA BUCKTHORN AND BUTCHER'S BROOM (F. E. J.).—We know of no way to distinguish between the male and female of these two plants when not in flower or fruit. It is necessary to grow both sexes together to obtain fruit. In the case of the Sea Buckthorn shoots of the male are sometimes grafted on a female tree. The Butcher's Broom is usually but not always unisexual.

TREES FOR HEDGE SCREEN (N. B.).—Two of the best quick-growing evergreen trees to form a screen are Thuja plicata and Cupressus Lawsoniana. There is very little to choose between the two, the latter is the more ornamental tree, though the first named would probably form a hedge quicker. For an immediate effect the best tree to plant would be an upright-growing Poplar, Populus alba pyramidalis or P. nigra pyramidalis are both deciduous, but the twiggy growths are thick and soon form a screen even in winter. Either of these could be planted now, 10ft. or 12ft. in height. April or May is the best time to transplant Thuja and Cupressus.

COTONEASTER PANNOSA (H. E. W.).—This is a suitable shrub for a hedge, though our correspondent will find it rather more robust than Berberis stenophylla. This, however, can largely be overcome by pruning. Cotoneaster pannosa forms an evergreen bush 10ft. or 12ft. high, so no difficulty will be experienced in making a hedge 6ft. to 7ft. high. Planting 4ft. to 5ft. apart would be sufficient, but careful training is necessary in the early stages to ensure there should be no gaps at the bottom, as C. pannosa does not make growth freely so low down as Berberis stenophylla. Another useful evergreen flowering shrub for a hedge is Escallonia langleyensis.

TREATMENT OF ROMNEYA COULTERI (W. M.).—It depends on the size of the plants and the length of the roots whether it would be preferable to pot the plants now and plant outside later or plant at once in the flowering position. Small pieces would be best placed in pots in a cool greenhouse, but those with long and thick fleshy roots should be placed at once in the flowering positions. We have not heard of the successful culture of Romneya Coulteri in pots. The conditions under which this plant thrives outside suggest that it would not make a good pot plant. Select a sheltered, sunny position at the foot of a south or south-west wall or fence, for instance, where the soil is fairly light and very well drained. Work in some leaf-mould and coarse sand if required when planting if the ordinary garden soil is at all heavy. A mulch of half-decayed leaf-mould would be beneficial. April is preferable to now for planting, but some pieces should grow now.

FLOWERING SHRUBS FOR BEDS (E. A. G. M.).—Two beds each 53ft. by 19ft. would require about one hundred shrubs in all. For the first two or three years after planting a thin sowing of annuals or such plants as Foxgloves and Honesty could be effectively made between the shrubs. Deciduous shrubs: Berberis polyantha, B. Wilsonae, Buddleia globosa, B. variabilis, Corynthus Gloire de Versailles, C. Marie Simon, Cornus spathulifolia, C. strobilata variegata, Cotoneaster frugida, multiflora, Simonsii, Cydonia japonica varieties, Cytisus albus, C. nigricans, C. praecox, C. purpureus, C. scoparius and var. Andronicus, Daphne Mezereum, Deutzia in variety, Diervilla Abel Carriere, Eva Rathke, Mont Blanc, Forsythia spectabilis, Fothergilla major, Genista hispanica,

G. tinctoria fl. pl., Hamamelis mollis, Hydrangea paniculata grandiflora, Hypericum Henryi, Kerria japonica fl. pl., Magnolia conspicua, M. stellata, M. Soulangiana, Philadelphus in variety, Prunus sinensis fl. pl., P. trilobata fl. pl., Pyrus floribunda, Ribes aureum, R. sanguineum, Rosa Hugonis, R. Moyesii, Spartium junceum, Spiraea in variety, Staphylea trifolia, Syringa (Lilacs) in variety, Tamarix pentandra, Viburnum Carlesii, V. Opulus sterile and V. plicatum. Evergreen shrubs: Berberis Darwinii, B. stenophylla, B. Aquifolium, Cistus laurifolius, C. cypricus, Cotoneaster Henryana, C. horizontalis, C. pannosa, Escallonia langleyensis, E. Philippiana, Hypericum Moserianum, Ilex Aquifolium (Hollies) argentea regina (Silver Queen), marginata regina (Golden Queen), Olearia Haastii, Osmanthus Delavayi, Rosmarinus officinalis, Veronica Traversii, Viburnum Tinus and Yucca gloriosa.

ROSE GARDEN.

SWEET BRIARS (F. E. J.).—It may be desirable to shorten some of the shoots this spring, being newly planted, to make sturdy bushes, but it is not usual to prune the Sweet Briar as one does ordinary garden Roses.

WEeping ROSE (F. E. J.).—Grass an Euphrasia and American Pillar are both hardy and good growers. American Pillar would make the better tall weeping standard. Our correspondent will find it necessary to shorten some of the longest growths at first to form a good foundation.

THE GREENHOUSE.

PRIMULA MALACOIDES ATTACKED (A. V. W.).—The Primula has been attacked at the collar by a fungus, which is the cause of the rot. In all probability the plant has been growing in conditions which have caused moisture to accumulate there, and this has enabled the fungus to gain a footing and carry out its destructive work.

CINERARIA FOLIAGE ATTACKED (E. B. J.).—The leaves are being fed by the grubs of a small two-winged fly. Pinching the ends of the tunnels where the grubs are feeding between the finger and thumb will be the best method of dealing with the insect if only a few plants are involved. If many, spraying with a nicotine wash would be wise.

FRUIT GARDEN.

CLEARING OLD BARK FROM FRUIT TREES (F. E. J.).—Only the really loose bark should be removed from fruit trees, and great care must be taken to avoid injury to the trunks. A dog chain may be used in experienced hands, but a piece of new cart rope is better still and not as liable to cause injury to sound bark. We do not know of special chains being sold for this particular purpose.

TREATMENT OF SLOES (F. E. J.).—Sloes usually fruit in the hedgerow. They must be growing in a poor position not to fruit with our correspondent, though facing south they are apparently much overbearing by the hedge. Our correspondent should clear the worst of this away and thin the Sloe bushes a little (described by him as a thickset). It might also be worth while clearing the ground beneath and mulching with some old decayed manure. The point to aim at should be to improve the growth this year and mature fruiting spurs for next year's flowering.

NAMES OF FRUIT.—G. P. T.—Apples: 1. Upton Pym; 2. Munchall Crab.—H. M. L. Rogers.—Pear Marie Louise. This variety will not keep long after Christmas. The very bad Pear season is no doubt responsible for the poor ripening and quality.—H. Rob.—Apples: 1. Winter Greening; 2. Hubbard's Pearmain; 3. specimen too bruised and malformed to identify; 4. Bedfordshire Foundling.

NAME OF PLANT.—W. T.—Rhododendron dauricum atrocinereum.

CATALOGUES RECEIVED.

Messrs. Blackmore and Langdon, Bath.—Begonias, Delphiniums, Gloxinias, Cyclamens, etc. Well illustrated in black and white and colour.

HOW TO PRUNE ROSES & FRUIT TREES.

A most helpful booklet by OWEN THOMAS, V.M.H. Sent post free on receipt of 11d. "COUNTRY LIFE" Offices, 20, Tavistock Street, Covent Garden, W.C.2.

STORING VEGETABLES AND FRUITS,
with chapters on "Drying in the Oven and by the Kitchen Fire." By HERBERT COWLEY. 9d. net, by post 11d.—Published at the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

You can't Dig a Garden—

with good intentions and a hairpin. There has to be some honest spade-work.

You can do your digging and weeding with anybody, but you have your little weakness like the rest of 'em! You like to *look* as though you'd done it. A little perspiration, and good honest dirt thick up to the elbow.

Well, and why not? Just walk about a little where the neighbours can see you, and then—KIT.

KIT soap will clear every atom of dirt, grease, oil, paint or tar out of your hand, and will do it nearly twice as quickly as anything else. It is a nice "spready" sort of soap, so you need only a little. The tin is blue and orange (the handy shape and the handy size), and the lid comes off just when you want it.

Keep a tin in the house for cleaning after "odd jobs."

Price 6d. per Tin.

KIT *the speed soap*

THE PRIMULAS OF EUROPE

With Botanical Classification, Descriptions, and Cultural Instructions

By JOHN MACWATT, M.B.

Crown 8vo., Cloth, 12/6 net; Postage 9d. extra.

The aim of the author has been to produce a handbook that will assist in the identification of those species of the genus *Primula* which are native to the European continent, and at the same time to furnish practical guidance to the cultivation of such of them as have been introduced to our gardens where conditions differ so widely from those prevailing in their natural habitats.

Dr. MACWATT is an acknowledged authority on Primulas, and his book presents in a concise and interesting manner the results of many years of close personal observation and experience.

"Increased Productivity Series"

First Advice to Would-be Farmers

THE Book for Allotment-Holders
and Smallholders

By F. E. GREEN.

Crown 8vo. 5s. net; by post 5s. 6d.

THIS book throws a flood of light upon those things which everybody wants to know before farming even a few acres. The author discusses sites and markets, the most profitable kinds of Small Farming and the practicability of side-lines and trades created by the new conditions. It is a book of absorbing interest and enormous help to all who wish to make a living from the Land.

No. 2673.—VOL. LXXXVII.]

[FEBRUARY 10, 1923.]

ROCK GARDEN CONSTRUCTION—I.

THE construction of a rock garden divides itself naturally into two parts, which we may call the general and the particular. These bear much the same relation the one to the other that, in warfare, strategy bears to tactics. First of all we must decide the general scheme of the garden—its hills and valleys and passes and, it may be, its brooks and pools. We must visualise, too, the general effects of planting, since on them much depends. Having as it were rough-hewn our rock garden, we have the detail work still to do, especially the placing of the actual stones. The difficulty of this last depends largely upon the class of material employed, but the arrangement and placing of the stone is, in any event, of immense importance. No beauty of idea will in any way compensate for an improbable or unnatural disposition of our materials.

To day let us discuss the general design, leaving for a subsequent article the equally important detail work. Now, to great extent, the form of the garden must depend upon the site on which it has to be placed. Let us commence, therefore, by defining the conditions which are necessary and also those which are very desirable in a rock garden. First of all the rock garden should be wholly or, at any rate, very largely free from the shade of trees; if genuine alpine plants are to be grown this is absolutely essential. Secondly it is very desirable that a small rock garden should run from north to south; this provides, without special care, that the greater number of sites will have an easterly or a westerly exposure, which aspects, in our climate, suit the majority of rock-garden plants. Thirdly, it is advantageous, especially where the garden is to be small, that there should be a

natural difference in levels between the two ends of the garden. Fourthly, it is preferable for this fall to be from north to south, rather than *vice versa*. Fifthly, a solid background of trees or shrubs at the northern end is desirable and a screen of trees at a little distance on the eastern side is also beneficial. The value of this screen depends upon its being at just the right distance, so that, while keeping no valuable light and air from the plants, it is yet sufficient, in early spring, to prevent the rays of the newly risen sun striking upon and scorching frozen blossoms.

Beside the five conditions mentioned, there is the very important question of pure air, but since few of us select our habitation from the point of view of the rock garden, we may let that pass. There are some very charming rock gardens in quite suburban localities and if a few of the choicest plants "refuse," such species are not generally those which we class broadly as "effective."

Returning then to our "five points." Point I is absolutely essential; a rock garden *must* be in the open. Point II can be overcome by careful

arrangement of the stone; and by a judicious "handling" of the hills and valleys we can provide the aspects desired in a garden running east and west, particularly if there is a fair width of ground to play with. An expert will readily overcome the difficulties suggested by Point III and provide a charming and natural looking rock garden on what was originally a dead level site, but special care is necessary to work such into the general garden scheme. There are many places where the suggestion of a sandstone outcrop would look quite satisfactory and yet an elaborate garden of weather-worn mountain limestone would appear absolutely ridiculous. With regard to Point IV, a steep fall from south to north is a very great drawback; a slight one, given careful arrangement, is of little account. Proper backgrounds must be provided if the rock garden is to be a success. To that extent Point V is an essential one; but, fortunately, such backgrounds can always be provided, though the effect of matured shrubbery or woodland cannot, of course, be obtained forthwith. Few will have the screen belt in just the right position

to eastward; great numbers will be quite unable to provide it. These must take special pains to provide shade from the east at various spots in the garden itself.

Now let us consider a couple of typical sites and discuss methods of laying them out advantageously as rock gardens. Fig. 1 shows the portion nearest the back of the house of such a rectangular strip as is attached to many thousands of houses in the County of London. A dry walk leads to the kitchen garden on the west side—it is supposed that the front of the house faces south—and a simple treatment of lawn and border is the only ornamental feature. Such an arrangement, if undistinguished, is at least not distracting.

A GLIMPSE OF A NEWLY BUILT ROCK GARDEN IN WATER-WORN LIMESTONE.

FIGURE 1.

FIGURE 2.

Now the occupier of the house—perhaps a new owner—wishes to include a rock garden. How is this to be done? Fig. 2 provides a solution, worked out for a level or practically level site.

The opening from lawn to rock garden is opposite the garden entrance to the house. The paths in the rock garden are of turf, from which the various plantings are made to rise as naturally as possible. The central area of turf is hollowed out ("dished") to a considerable extent and the soil removed is used for building up the banks as shown. A moderate amount of "dishing" and the consequent use of material from outside the garden to complete the mounds is desirable, but if necessary steps can be introduced as required and the whole of materials excavated on the site. When thus contouring ground it is necessary always to bear the question of drainage in mind and if this is at all doubtful, to improve it.

The central mound of rockery will inevitably be in full view of the house windows and will serve to close the vista from the house across the lawn. It is necessary then to plant some interesting shrub or group of shrubs to mark the termination of the vista and to arrange the supporting planting on either hand to give a balanced effect. Owing to its pleasing greenness when devoid of foliage and other goods points for the position, *Cytisus praecox* comes at once to mind for this central feature, but a specimen dwarf conifer, a clump of *Kerria japonica* simplex or many other things would also prove suitable. The character of the planting in the shrubbery dividing lawn from rock garden would naturally influence one's choice.

This view across the lawn should be the first garden picture to receive consideration; it is a very important one. Once inside the rock garden a succession of pictures should be arranged and as great a variety as possible should be sought for. In a small garden such as this and on what was naturally a level site, "pass" effects are scarcely feasible. The paths will follow the lowest ground leaving cliffs or rocky slopes upwards on either hand. In the diagram two moraine slopes between more or less precipitous cliffs are shown on the north side (looking south) and marked "A." One of these projects outwards a little from the cliff in the hollow lawn, the other retreats somewhat up its channel and a loose piece of rock bedded in the sward (and probably overplanted with a dwarf Juniper) marks the continuation of its course. On the west side of the garden a similar outlying rock marks the termination of another small moraine or stony peat bed with a north aspect. The use of this will be explained when detail construction comes to be considered.

No exact rules can be given for forming the garden pictures already referred to—so much

FIGURE 3.

depends upon the class of stone and the specimen plants available, but those with the ability to make a satisfactory sketch will find their gift exceedingly helpful. Others will have to form their pictures and here the commonest and ugliest things may be pressed into service to assist the judgment. Given a few suitable dwarf shrubs and what not and a little imagination, a Tate sugar box or two may be used to determine the

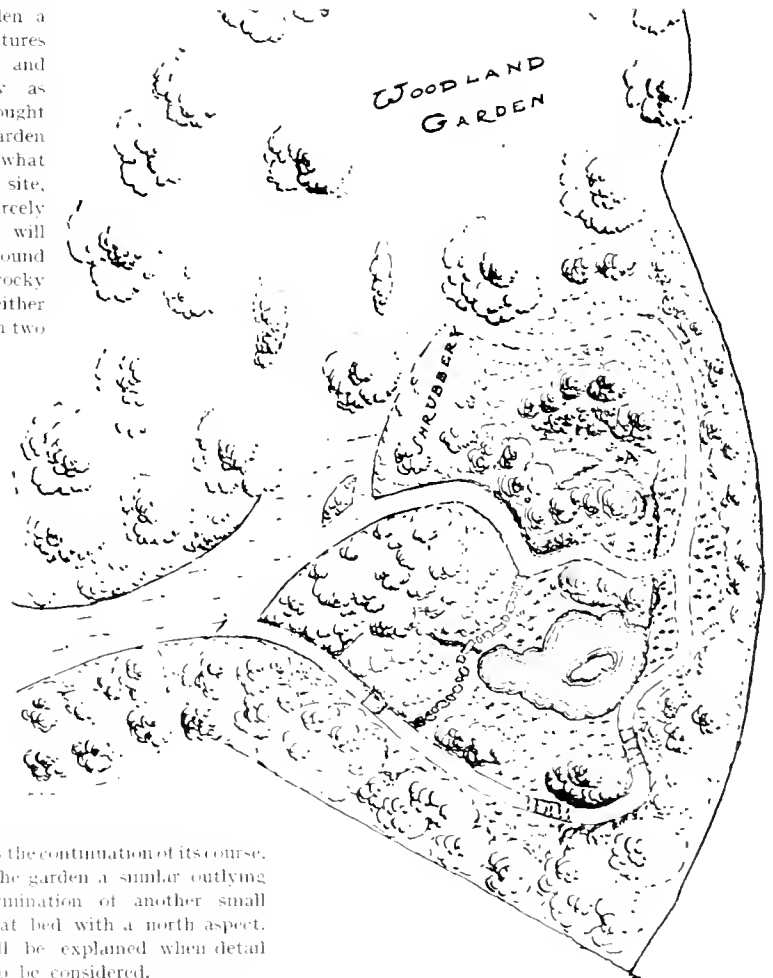

FIGURE 4.

best place for a precipice with much less labour than would be involved in repeatedly setting up and taking down stones for the purpose!

In Fig. 3 is shewn an entirely different site. A small spinney here was just outside the garden scheme of a newly-erected country house. The great possibilities of this spinney for a woodland garden were borne in mind and the owner very wisely connected it to the gardens proper by attractive but semi-wild shrubberies bordering an artificial grassy glade.

When, in time, the gardens as laid out got into thorough working order, the inevitable mistakes had all been rectified or, as far as possible, disguised, it was felt that the addition of a not over-large but well designed rock garden would be an improvement. A suitable site presented itself between the garden proper, the converted spinney and the connecting shrubbery. Fig. 4 suggests the treatment that was accorded. There was a slight fall from the connecting glade down to what was to be the boundary of the rock garden and this was accentuated by skilful planting and also by rather subtle contouring. The path at the bottom of the garden was excavated to assist to form an irregular bank against the field. Further excavation outside the boundary lifted the bank further and with the assistance of the usual brickwork completed a ha-ha.

The soil excavated for the pool shewn was devoted to forming the "highlands" which at the east end surround the moraine marked "A," and which at one point terminate as a cliff against the central path forming, for the path is walled up on its western side, a "pass." At the western corner of the garden, as the steps in the curving path would suggest, there is another highland through which, despite the steps, the path is taken in a cutting. As one goes southward from this corner there is a cross glade giving a delightful view across the pool to the "highlands" beyond; then further shrubbery planting at the level of the path, or a little higher, again restricts the view. The stepping stones shewn on the plan, run at the foot of a bank—in places fairly steep, in others of quite easy gradient—which supports heavy planting, largely consisting of the original shrubbery. Down this bank splashes a miniature rivolet.

Another trickle of water may be discharged into the head of the moraine "A," a very desirable thing in droughty weather or may be cut off there and turned on just at the foot of the moraine. In either case it wends its slow way to the pond, to which there is, of course, fitted a drain overflow. Thanks to this trickle of water the soil on the north side of the southern path is always moist, not to say boggy, and a considerable piece on the south side of this path is also kept damp by the same means. This moist ground suits a great variety of *Candelabra Primulas* and semi-bog plants. Reverting for a moment to the central path, immediately below the cliff already referred to there is a wide bottomed valley, planted partly with Heaths and partly with bogland plants and on the opposite side of the path and dividing this latter from the pool a ridge capped with large-growing Heaths and *Rhododendron* species.

At the eastern end, the garden dies away into the woodland, the ground gradually becomes more level and an occasional happily placed rocky boulder serves to connect the two styles of gardening without any hard and fast line. There are many plants which like the situation thus provided. It will readily be seen that a rock garden such as this, small though it be, contains situations suitable for an immense variety of plants and that without any appearance of forced effect. Because of the variety it offers we shall hope, in a future article, to detail some of the construction and planting.

SOME CHOICE ANNUALS FOR SPRING SOWING

NOW that the seed lists are in and orders must be sent out, a few suggestions regarding annuals may be of service to amateurs, who are often at a loss to know what to select. Omitting all or most of the better-known annuals—those commonly grown by the majority—I will confine the following notes to a number of desirable species and varieties which, though generally as easy as the more familiar ones, are seldom seen in the average garden.

Consider, for example, the annual *Lupinus*. Here is a class that affords a wide variety of wonderfully showy plants which are admirable for border or bedding, easy to grow and adaptable for almost any soil, yet one very seldom sees them anywhere. The crimson-scarlet hybridus *atrocoeruleus*, *Cruikshanksii*, *Hartwegii* and sub-*carneus*, a fine blue, are among the most noteworthy and range in height from 1ft. to 2ft. Then there are among the Evening Primroses (*Oenothera*) a number of handsome species which are well worthy of wider

are probably most successful if treated as rather tender "half-hardies." That is to say, it is wiser in most districts to bring them on early in a frame or even in a heated house and to put them out against a warm wall in May or June. They enjoy plenty of old cow manure and moisture. If a westerly aspect is given them, the flowers, which otherwise go off early in the day, will remain open till noon.

The exquisite, clear blue tones of some of these *Ipomoeas* remind one of the blue annual Pea (*Lathyrus azureus*), a delightful little climber of some 4ft. which will yield throughout the season a succession of large azure blossoms suffused with rosy tints. This may be sown where it is to grow and it ripens seed freely for the following year. Yet another good blue is that of a tiny annual of quite another kind, *Sedum caeruleum*. A few pinches of its seed scattered about gritty, sunny spots in the rock garden will bring an ample reward. Some grow this charming little thing in cool, rather damp places, but we find full exposure

A BEAUTIFUL WHITE EVERLASTING, RHODANTHE MACULATUM ALBA AT GRAVETYE.

appreciation, *Oenotheras triloba*, *Drummondii*, *odorata* and *maxima* all being good and asking no more than ordinary half-hardy annual treatment.

For a hot place, well drained, there are few annuals to approach in beauty *Calandrinia grandiflora*, with its large, fleshy leaves in a peculiar jade green, red stems and big, crinkly poppy-like flowers in rose pink which nod at the tips of the thin stems. Once seen, this splendid Rock Purslane will never be omitted from the seed list. Readers who are not outraged at the presence of magenta may also try *C. umbellata*, treating it as an annual; also the brilliant crimson, *C. Lindleyana*.

Convolvulus minor (tricolor) affords a whole list of attractive colours—light and dark blue, rose, violet and white—all of which are good and easy and not usually exceeding 1ft. in height. These are attractive for the front of the border, where they can disport themselves among such plants as have gone out of flower—*Aubrietias*, for example. The same genus gives us the wonderful "Morning Glories" (*C. major*) with their gorgeous trumpets of various vivid colours which adorn the roof, stems from midsummer to the first frost, the indescribably lovely *Ipomoea rubrocaerulea* and the exquisite blues of *I.hederacea*. These

and a free soil gives more certain results, and under such conditions the leaves and stems become stained with a more brilliant crimson.

Also for hot, dry situations in the rock garden or front of the border we have those diminutive (vin.) *Eschscholtzias crispisoma* and *tenuifolium*, with delicate, carrot-like foliage, faintly glaucous, and pale yellow flowers which open flat like a Buttercup. For association with these in sunny places the *Leptosiphons* are first-rate, especially *LL. aureus*, *androsaceus* and the hybrids, all of some 3ins. to 6ins. in height. Seed of these may be dispersed at random in dry walls, about steps or flagged walks, or along the margins of paths. *Lasthenia*, a pretty Californian annual in various shades of yellow and deep orange, is also useful for similar purposes.

The velvety gentian blue of the *Phacelias* gives these latter high rank among the best of annuals, but they are not everybody's plants. Though not really difficult, even when sown direct in the open, *Phacelia* has not a good reputation with many. In our experience such kinds as *PP. campanularia* and *Douglasia* prefer a light, sandy soil and not too much sun. A spot that would suit their fellow countryman, *Nemophila insignis*, to which the *Phacelias* bear some resemblance, should

satisfy them. The probability is that many failures may be attributed to slugs, which will travel far for *Phacelia* seedlings. In their own country (California) plants of this genus may often be seen cropping up in the ashes of forest fires (a hint here for the use of burnt soil and wood-ash) and not a few grow on calcareous soils in great abundance.

Those who have a weakness for annuals of the "Everlasting" class should try some *Rhodanthes*, pretty, glaucous-leaved plants of about 1 ft. which should be raised early under glass and pricked out young in good soil. *R. Manglesi* in rose and *R. maculatum*, vivid carmine, white and other colours are both reputable kinds. *Erysimum Perofskianum*, of 1 ft. or more, will yield handsome racemes of orange yellow, wallflower-like blossoms towards the end of summer, and the clear rose *Eucharidium Breweri*, brought on in March and put out in masses later on, will give an effective and uncommon display. Perhaps the dahlia-like *Cosmos bipinnatus* is too well known to need mentioning here, but it is such a beautiful and useful plant for the autumn border that it should not be overlooked. Few annuals are more easily raised, but *Cosmos*, in all its various forms and colours, needs to be raised under glass, otherwise the season will be short. *Statice sinuata hybrida*, in a number of colours, is well worth growing. It should be treated as the last mentioned and grouped in the front of the border.

The *Linaria* group provides us with several very lovely annuals of about 1 ft. which do well sown in groups in the open ground in spring. *L. multi-punctata*, dark chocolate or black, speckled with yellow, is one of the prettiest. *L. aurea-purpurea* has flowers in various shades of rich orange and purple. *L. bipartita* var. *splendida* can also be recommended, and there are a number of very showy hybrids. All of these are easy, good-tempered plants in any free soil with full exposure.

The Swan River Daisies (*Brachycome*) comprise another little family of annuals from Australia which grow to about 6 ins. and fully reward one for the trouble of bringing them up in gentle heat, like *Cosmos*. A mixed packet will give a wonderful variety of bright colours, but those who prefer to grow the species apart may rely on *BB. iberidifolia* in blue (Little Blue Star), the newer Summer Beauty (mauve), Snow Star and Purple King. For a hot, dry place *Bartonia aurea* (*Mentzelia*) is admirable, its big golden cups nestling in handsome foliage. Nor should one omit a selection of the beautiful South African *Arctotis*. *A. grandis* is one of the finest of these with grey foliage and large daisy flowers with a lavender eye and long white rays starting from a yellow basal ring. A well grown plant of *A. grandis* will reach 2 ft., but early sowing in heat is essential, and a warm spot when planting out should be chosen. Another annual of the same character, also from South Africa, is the Namaqualand Daisy (*Dimorphotheca*), a most attractive plant in all its forms, the soft shades of golden buff, orange, cream and salmon-pink of the several varieties being accentuated by a centre of black or other dark colour. *D. aurantiaca*, with orange-salmon rays and dark eye, is the type species of most of the hybrids.

Sanvitalia procumbens is a neat little yellow Composite for late blooming, the double form being perhaps more effective than the single. Yet another of the same Daisy family is the Mexican *Sphenogyne* (*Ursula speciosa*), which will yield an abundance of blooms in the later summer in shades of yellow varying from lemon to a golden buff. The habit is semi-prostrate, or spreading, the many slender growths rising to a height of about 6 ins. In striking contrast

to the flaming tints of the foregoing is the chaste and refined *Onophalodes linifolia*, with foliage of a cool sage grey, soft as kid, and large forget-me-not flowers in a glacier white. *O. linifolia* is so easy, such an everlasting bloomer and so curiously attractive that we are never without a few good groups of it. It grows to about 1 ft., and may be sown where intended to grow. In many gardens it comes up year after year from its own September-sown seeds. The very charming campanula-like *Specularia Speculum*—dreadful name for a thing so sweet and modest!—will also sow itself in favoured gardens, but where

A GORGEOUS CLIMBING ANNUAL,
CONVOLVULUS MAJOR.

it does not, a fresh two-penn'orth of seed each spring should be everyone's resolve. *S. Speculum* is a slender habited, semi-trailing annual with bells of gorgeous violet. There is a form with blossoms much larger than those of the type, and a double one which is less pleasing than either of the singles. *S. pentagonia* we have not yet tried, but it is said to be admirable.

For massing in groups for a bold effect, what is there in the taller annuals better than the Mallowworts (*Malope*)? I have seen them well grown in beds, and they are first-rate for filling up blanks in the borders of late summer. *M. grandiflora* is one of the most showy, the large, glossy flowers being a rich blood crimson in the type, satiny rose in the variety *rosea* and white in

alba. *Malopes* may be sown in the open, but, like Hollyhocks, they enjoy good feeding and so should have a deep, liberally prepared bed. They go up to about 2 ft. *Scabious* may be mentioned here as being about the same height as the above and most useful for border work; but, well known as the annual *Scabious* may be, it is not often that one sees other than the dull reds and crimsons. In addition to these there are some extremely handsome varieties in shades of coral, yellow and lavender, one named Fairy (if memory can be trusted) rivalling the superb *S. caucasica* in the exquisite delicacy of its blue-lavender flowers.

The Pimpernels (*Anagallis*) include some fascinating little plants in a variety of rich colours—blue, purple and ruby red—and these may be easily grown in any vacant spots in the rock garden. Nor can one pass by the claims of *Whitlavia grandiflora*, perhaps one of the best things we have had from the home of gay annuals—California. *W. grandiflora* attains the height of some 12 ins. and bears a crop of fine large bells in an intense blue.

The species may be sown where it is intended to grow, a light, friable soil being desirable. With the mention of yet one more Californian this list must be closed, conscious as I am of many omissions. I refer to the splendid *Argemone* (Prickly Poppy), very choice and distinguished with its big, white, golden-centred Poppy flowers adorning its 2 ft. stems. In its own favoured land *Argemone grandiflora* is, I think, perennial, but it is as an annual that most of us here must consider it. Even so, it is well worth the trouble of raising the seedlings in heat, well worth the choicest and warmest corner and the kindest soil.

A. T. J.

THE WHITE 'PERUVIAN DAFFODIL'

LOVERS of summer-flowering bulbs should, when ordering, not omit to secure a few bulbs of the beautiful "Peruvian Daffodil," *Ismene calathina*. The average garden dictionary quotes it as a stove and greenhouse plant, but in reality it flowers splendidly out of doors. The best plan is to pot up the bulbs about March and stand them in a cold frame. Growth is somewhat slow to start, but by the latter end of May the foliage will be several inches high, and the plants may then be turned out. During June the growth is very rapid, and almost before one realises it the glorious snow white trumpet-shaped flowers are out, each stem bearing two.

The flowers are not unlike a Daffodil in shape, but the perianth segments are narrow in comparison with the trumpet. Moreover, the stamens are not in close touch with the pistil, as on the Daffodil, but are attached to the inner side of the trumpet.

Any ordinary soil is suitable, and on fairly light soils the bulbs may be planted in the open when dormant. Indeed, to keep up a succession, it is a good plan to pot up the first batch and plant others in the open when planting *Gladioli*. Of course, this delightful, yet rarely seen bulb makes a fine pot plant. Like other members of the *Amaryllis* family it is increased by offsets. The bulbs should be lifted by early October and thoroughly dried off, as only by forcing them to rest can they be made to flower annually. The bulbs are quite cheap; certainly no more costly than cores of a good *Gladiolus*.

T. A. W.

ALPINES AT CHISLEHURST

A CASUAL word from an alpine lover who had been there sent the Editor recently to visit the Chislehurst nursery of Mr. G. G. Whitelegg. It is a long while since he remembers time passing so quickly as it did while, in company with Mr. Whitelegg himself, he made the tour of the frames and houses devoted to alpinists. It was only when he had finished the inspection and came to collect his impressions that he realised what a very large proportion of the plants were what one considers choice alpinists and how very considerable a proportion of the stock represents really scarce plants.

At the time of the Editor's visit stocks of *Aubrietias*, the commoner Mossy Saxifrages and similar furnishing plants were doubtless at rather a low ebb, for such things are planted mostly in autumn, winter and early spring. An immense number of the best varieties of *Aubrietia* were, indeed, in the propagating cases, and an especially good strike was in evidence. Still, ebb or flow, the Editor must have seen plants which could (given time!) be numbered by the hundred thousand, and an overwhelming proportion represented really choice alpinists—*Kabschia* and *Engleria Saxifrages* with some of the very choicest of the Encrusted section, *Ramondias*, *Gentians*, *Haberleas*, choice *Primulas*, the better Alpine Pinks, *Silene acaulis*, *Potentilla nitida*, *Aquilegia pyrenaica* and *A. glandulosa vera*, *Asperulas*, choice *Campanulas*, the choicest *Drabas*, *Incarvilleas*, *Lithospermums*, *Onosmas*, alpine *Ranunculi*, *Sempervivums*, including the strange *S. spinosum* (more accurately *Cotyledon spinosa*), *Shortias* and *Soldanellas*.

Now for a few detailed impressions! The choicer Saxifrages are evidently favourites of Mr. Whitelegg. Among the Encrusted sorts a very fine batch of specimen longifolias, owing to their size, claimed first attention, but a moment later a stock of a form of *S. Cotyledon* with huge rosettes proved even more interesting. Broader in the leaf than the plant generally known as

S. Icelandica and even larger in the rosette, this splendid form is known as *S. C. platyphylla*. Some hybrids of *Saxifraga longifolia* of Mr. Whitelegg's own raising were also very attractive. Attractive, at any rate, as regards foliage, for some of them were as yet unflowered. These were large rosetted sorts, quite different from the fine longifolia hybrid Cecil Davis, also stocked, which has comparatively small rosettes. Of the more ordinary "Encrusted" there is little need to write.

Coming to the *Kabschia* varieties, the Chislehurst nurseries contain a good stock of *Saxifraga valdensis*, which is not *S. cochlearis minor*. Mr. Whitelegg, indeed, prides himself upon the trueness of his stock, and points with pride to true stocks of such plants as *Draba rubricata*, *Aquilegia alpina*, and *A. pyrenaica* and *glandulosa*. Out of a host of other tufted sorts, including such excellent hybrids as *Petralschii*, *Paulinae*, *Faldonside*, *Cherry Trees*, etc., we remember noticing *SS. Boydii*, *thessalica* (vera) and *lilacina*, the two former because, whatever catalogues may suggest to the contrary, they are uncommon and the last because of its minuteness.

THE EXQUISITE BLUE *AQUILEGIA ALPINA VERA*.

Saxifraga lilacina bears to the ordinary run of Tufted Saxifrages the same relationship that, among the Porphyrians, the close-growing *S. retusa* bears to the more luxuriant forms of *S. oppositifolia*. Mention of *S. oppositifolia* brings to mind Mr. Whitelegg's opinion that of all the *oppositifolia* forms *S. o. W. A. Clark* is the best and finest.

While inspecting Saxifrages a few plants of a miniature order, obviously a *Tsuga*, but unknown to the Editor, attracted attention. This is the rare *Tsuga Albertiana conica*. It is only fair to state that Mr. Whitelegg has a very fine lot of miniature conifers of many kinds, including beautiful plants of *Cupressus obtusa nana* and some fine specimens—oft. or roft. across—of *Juniperus prostrata*.

There are thousands of *Ramondias*, including a batch of the rare but not specially beautiful pink form. Some of these plants are collected specimens, others from seeds, but all in full health and vigour. Of *Aquilegia pyrenaica*, again, a large breadth and many thousands of tiny seedlings which will be splendid plants by another season. The beautiful *Ranunculus glacialis* is another plant of which a large stock is held, while there are also several hundreds of plants of *Primula integrifolia*, some of them, so Mr. Whitelegg said, splendid colour forms. In another house, mostly noteworthy for thousands upon thousands of the best and choicest *Campanulas*, from the glorious *Allionii* and the tiny *Waldsteiniana* to such beauties as *pulla* and *pulchra*, one paused instinctively to query a batch of unidentified growing points—just piercing the soil. These, it seems, represented the tiny rhizomatous *Iris arenaria*, with soft yellow

THE BEAUTIFUL SUB-SHRUBBY WHITE-FLOWERED *DRYAS OCTOPETALA*.

flowers, a plant about which Mr. Whitelegg waxed enthusiastic. Attaining a height of only pins, or so, an established plant will continue to produce its attractive blossoms for a period of six weeks in springtime. It was here or hereabouts that a healthy batch of Kurume Azaleas attracted attention, mainly the splendid varieties *Hidemanyo* and *Hinode-giri*. The nursery holds a very large stock of the *Candelabra Primulas*—*P.P. helodoxa*, *Bulleyana*, *pulverulenta*, *pulver-*

lenta hybrids (*Lissadell*, *Adm. Aroon*, etc.) and *japonica*—and also of *Gentians*. Of these last Mr. Whitelegg's favourite is *G. Lagodechiana*, and who shall say that he displays bad taste! The lovely *Lithospermum rosuarnitolum* is another favourite. What a pity that it is not truly hardy in most counties.

One could write pages about other interesting plants, especially the tiny seedlings of all sorts of choice alpinists, including *Saxifragas*, *Primulas*,

Ranuncias, *Haberleas*—wonderful batches—*Gentians*, etc., always attractive to an alpine lover, but we must forbear.

Enough has already been written to show that for anyone who really knows and loves alpinists a visit to the Chislehurst nursery now would provide a treat. Those with perhaps equal enthusiasm but less knowledge would be wiser to wait a few weeks until there is a greater show of bloom.

SPRING FLOWERS AT VINCENT SQUARE

IN the unofficial opinion of the chairman of the Floral Committee a record was created at the meeting of the Royal Horticultural Society on January 30 in that there was not even one solitary novelty plant or flower for his committee to sit upon in judgment. Nor can we, in a considerable experience of R.H.S. meetings, recall such another blank day in this respect, though we remember on a dull day in drear December some years back when, in response to the expressed desire of certain Fellows, the Council called the committees together on a Tuesday before Christmas in order that no valuable novelty should go uncertificated because it was so misguided as to bloom during that four weeks or so when no R.H.S. meetings are held. On that occasion one solitary plant, devoid of merit, was sent, so the experiment was not repeated. On the present occasion no award was made to a novelty by the Fruit and Vegetable Committee, but the Orchid Committee made several awards to new Orchids. The exact number is somewhat a matter for conjecture. The official list, which was posted on the notice board in the vestibule, gave the names of three new varieties and their exhibitors, but in the hall only one could be found, though two other varieties had award of merit cards, but their names were totally different from those on the official list.

The floral groups in the hall were of a decidedly spring-like character, and although several exhibitors had for various reasons to cry off at the last moment, it was quite a bright and interesting show. The vacant places were filled with exhibits of garden sundries, photographs and paintings of flowers and garden scenes. The most valuable and interesting exhibit in this category contained water-colour drawings of British fungi by the late Mrs. Richard Gill. These were of great artistic merit and correctly named. Mr. R. H. Malby had a wonderful collection of photographs of Cones on their branches, mainly of Pine, Fir, Spruce and Cedar.

Among the flowers the early Frises were very prominent. *Tris reticulata* and *T. tingitana* were well shown by many exhibitors; while Messrs. William Cuthbert and Sons had particularly good plants of the dwarf, sweetly-scented *Tris Sind-pers*. Messrs. Carter and Co. made an artistic display with large bowls of *Tris tingitana*, *Primula malacoides*, *Princess Mary* and *Cynthella Hyacinths*. *Tris tingitana* is increasingly popular. The early *Primulas* were also of more than

passing interest. Messrs. Bakers, Limited, arranged a splendid batch of *Primula Wanda*, which is much like a larger and deeper coloured *P. Julia* and quite as free-flowering. The latter sort was also present in agreeable quantity. Messrs. Carter Page and Co. shewed it with Wilson's Blue Primrose, while Messrs. R. Tucker and Sons associated it with the fascinating *Primula Winteri*

pink *Schizostylis* Mrs. Hegarty. A brilliant batch of *Anemone fulgens* near a pan of *Crocus Susianus* was shewn by Messrs. Waterer, Sons and Crisp.

Some interesting varieties of the less-known Hellebores were contributed by Messrs. Barr and Sons, with alpinists and pots of double Daffodils. The Hellebores included *H. graveolens ruber* and *H. antiquorum roseum*. The white "Christmas Rose" was well represented by *H. niger maximus*, which Messrs. R. & G. Cuthbert arranged with their welcome *Cynthella Hyacinths*.

Camellias were again well shewn by Messrs. Chaplin Brothers, who have taken over Messrs. Paul's stock. Their neat plants were well flowered and, besides many doubles of merit, included *Mars*, a very large semi-double of reticulata colour; *Waltham Glory*, a brilliant single; *Snowflake*, an excellent pure white single; and the semi-double red *Apollo*.

Many good plants of *Azalea indica* varieties were associated with floriferous little bushes of *Prunus triloba* by Messrs. L. R. Russell, Limited. Messrs. Stuart Low and Co. also had some *Azaleas* with their *Acacias* and winter-flowering *Begonias* adjoining the larger collection of Carnations. *Cherry Ripe* and the pink *Eileen Low* were very attractive, while *Sheila Greer*, a pale apricot and rose-coloured tawny Carnation, was highly decorative.

Among the large collection of Carnations by Messrs. Allwood Brothers the vases of brilliant blooms of *Edward Allwood* were very prominent. *Vivid*, a new variety which suggests a *Mary Allwood* of flatter shape and much deeper colour, was very bright.

Vegetables were represented by a collection of Leeks from the Society's Wisley Gardens and some eighty baskets of Potatoes from Messrs. Sutton and Sons. These were all splendid tubers, and the coloured varieties interested many visitors, who seemed surprised to see in the cut tubers that the deep colour of *Black Prince* was continued in the flesh. *Royal Purple*, *Eightyfold*, *Mr. Breeze*, *Reading Russet* and *Border Queen* are the names of a few others of the coloured tubers. The very many white Potatoes were also of excellent quality. The Leeks were well grown examples of varieties which had received awards at the Wisley trials.

NEW AND RARE PLANTS.

Brasso-Cattleya Helen.—In colouring this hybrid Orchid favours the *Cattleya*, but the purplish mauve is rather brighter and clearer

WHITE-FLOWERED CAMELLIA SNOWFLAKE.

which Messrs. R. Gill and Son shewed with that earliest *Rhododendron* *Nobleanum* and *R. argenteum*. *Anemone blanda atrocarulea*, *Arabis aubrietoides* (bearing a goodly quantity of pink mauve-flushed flowers), *Soldanella alpina*, *Saxifraga Burseriana Gloria* and *Adonis amurensis* were very interesting among the alpine plants. The last named was shewn by Messrs. Wallace and Co., who again staged pans of the early *Crocus* species, excellent conifers and plants of the beautiful

than is usual in that genus. The broad, elegantly fringed lip is of the same colour as the remainder of the flower, but is enhanced by the patch of old gold on the basal throat. Award of merit to Mr. J. W. Bird.

Cypripedium Dulcis Lambeau's Variety.—An exceedingly handsome Lady's Slipper Orchid of rather more than medium size. Its chief beauty lies in the large dorsal sepal, which is beautifully waved and broadly margined with white; the colour is warm chocolate, shading to rosy purple. The wings and lip are coloured green and brown, and the former are margined with greenish yellow.

A very healthy and vigorous plant of this green-leaved variety was shewn. First-class certificate to M. Firmin Lambaert.

Odontoglossum Llewellyn. The plant bore a magnificent spike of well formed flowers set at regular intervals. The general colour is rich chocolate, and this is lightened by white markings and a broad white tip to the lip. Award of Merit to Messrs. Charlesworth and Co.

A HORTICULTURAL MARVEL

A Red Letter Day for Prepared Hyacinths.

READERS of old books about garden matters are conversant with the numerous receipts that are given with all seriousness to produce horticultural wonders of different kinds. I give one as an example from Adam Speed's "Adam out of Eden." The second edition of this small book was published in 1659 and Chapter XVIII is headed "To make five sorts of Roses grow upon one Stock without inoculation." This is how it was to be done. "When they begin to knot, bore with an Aul under the knot, and with a feather put Green in one, and Yellow in another. Red in the third, and Blew in the fourth, and close up all the holes handsomely." One smiles and wonders. More smiles and more wondering when, a few pages on, we are told how to produce yellow Roses. "The roots of Roses with their slips and knots removed and set amongst Broom, will bring forth yellow Roses." These I venture to think are marvels of the imagination only—perhaps my friend Mr. McGredy will correct me if this is how he produced his now famous Christine. The display at Haarlem, of which two views are given on this page, fore-dated spring by a good many weeks and was a real marvel. To have Hyacinths and Tulips in such perfection and in such quantities as were to be seen in the horticultural hall in that town on December 23, 1922, would have been almost unthinkable at the beginning of the present century, but I believe a similar display could be made any year now, not only in Holland, but in England.

The Tulips are those which experiment has shewn to be most amenable to this very early

flowering, helped with bottom heat and perhaps with some shade, if not total darkness, for a short time. The Hyacinths were all "Prepared Bulbs," and the display on December 23 last shews how great has been the advance in the methods of preparation. I can only say from my own personal experience what a valuable asset these prepared Hyacinths are to our gamut of early forced bulbs, even if they are treated exactly as ordinary ones and no special forcing treatment has been given them.

The following are the names of the best Hyacinths and Tulips shewn. Hyacinths.—White: Mad. Kruger, L'Innocence, Arentine Arendsen, Hein Roozen. Blue: Fürst Bismark, Gloria Forum Supreme (double), Lord Nelson (double), Gen. van der Heyden, Schotel, Verdi (large white centre, bold truss), Red and Rose: Van Tubergens Scarlet, Fen de l'Empire, Victor Emanuel, Nimrod, Moreno, Maria Catharina. Purple and Yellow: Distinction (deep purple), Laura (lilac), Yellow Hammer (yellow).

Single and Double Tulips.—Duc van Tholl (all varieties), Vermillon Brillant, Brillant Star, Mon Trésor, Rose Précoce, Salvator Rosa, Le Matelas, El Toreador, Fred Moore, Maes, Tournesol.

"PREPARED" HYACINTHS AT CHRISTMAS TIME.

Golden King, King of Yellows, Diana, L'Espérance, Lady Boreel, La Reine. JOSEPH JACOB.

A SWEET PEA SELECTION FOR 1923

THERE may still be many readers of THE GARDEN who have not yet made their final selection of Sweet Peas for the coming season. The present is a suitable time to sow the seeds under glass. My choice of varieties in the following article is not intended as a selection of the best, for that is almost impossible when individual tastes differ so much and when there are so many varieties nowadays of almost equal merit, but the list of names represents a large proportion of the most popular standard varieties and one or two of the outstanding novelties that I have found to be good.

Unlike many Roses, most Sweet Peas are equally useful for exhibition and garden decoration, but a few of the varieties are not capable of giving blooms large enough to win in strong competition, while the salmon, orange, orange-pink and orange-scarlet varieties need shading, which is sometimes rather detrimental from a decorative standpoint, so that, where necessary, I will give a variety specially recommended for the exhibitor and an alternative kind for garden decoration.

A white is usually desired, except by growers who live in smoky districts, where it would be preferable to substitute a cream variety. Constance

A "SPRING BORDER,"

Both pictures taken at Haarlem Show on December 23 last.

Hinton is undoubtedly the best white for exhibition on account of its great size and fine broad standard. It is always a good plan to grow a few extra plants of this variety, as some of the flowers are very faintly tinted with pink (although it must be said that the best stocks now have a very small proportion of these). Constance Hinton is a brown seeded white and it may never be possible to obtain an absolutely pure stock. In a wet or cold period Constance Hinton is not very reliable, as the young blooms have a greenish edge, but this gradually passes off as the flower opens. In a sunny season it is superb. Edna May Improved is the best pure white, and I would recommend it for general garden cultivation. It is a vigorous grower and gives some fine long-stemmed flowers.

A lavender is indispensable in an up-to-date selection. It depends whether rosy-lavender or pure lavender is preferred. Some say that the rosy tint gives a warm, pleasing effect, others that it is not as delicate as a self colour. Austin Frederick Improved and the old favourite, R. F. Felton, are both good rosy lavenders. I think I should choose the former if I had to decide between the two. Both are very vigorous growers and give four bloomed sprays in plenty. For a pure lavender it would be difficult to find a better choice than the novelty Powerscourt, which is certain to be one of the great Sweet Peas of the season. These three lavenders are good for all purposes.

I would recommend Matchless as the best cream for the exhibitor. It has entirely superseded Felton's Cream, being as vigorous and more frilly in the standard. Although Matchless can be used for decorative work I think I should prefer the pretty edged and flushed cream-ground Mrs. Wakefield for the garden, especially now that Mr. Unwin offers a new and much improved stock. It is a charming variety for table work.

Mrs. Tom Jones requires a fine season to bring out its bright blue colour. Then it has no equal. I choose it as No. 4 both for exhibition and garden.

Picture is such a delightful companion for it in the stand—I would always place them near each other, preferably in a front row—that it must come as the next choice. Its lovely deep cream-pink colouring, its great size and the ease with which four-bloomed sprays can be produced make it one of the most popular Sweet Peas in commerce. I have found that its colour improves if only soot water is used for feeding purposes in the flowering season. For those who prefer a pale cream-pink I cannot recommend a better variety than Cecily, a very fine all round variety.

It is difficult to say which will prove the better scarlet-cerise, the well known Royal Scot or the novelty Wonderful. One of them should be in every collection, as not only is the colour so rich, but both varieties are perfectly sunproof. If you believe in old favourites choose Royal Scot, if you prefer the novelty I feel confident that Wonderful will not disappoint.

Doris is my seventh choice. Like Royal Scot and Wonderful it is one of those rich, telling colours that does not fade in the hottest sunshine. A good grower, a sure four-bearer and the blooms well placed on long stems, this fine pale cerise or cherry-pink has many years before it. Under artificial light it is exquisite.

I have always considered that Hawthorn Pink has been rather disappointing, but now that there are some very fine stocks on the market it is worth growing for those unique, richly coloured pink blooms that instantly arrest attention. Even the best stocks give a low paler tinted flowers and the variety rather lacks vigour. One hardly knows whether to give eighth place to it or Hebe, an improved Hercules and a very fine exhibition variety, or Elegance, a beautiful lilac-blush, one of the most refined Sweet Peas we have.

No. 9 must be a dark variety, for the maroons supply the necessary balance of colour in a stand, and they are effective if mixed (in a small proportion), with a white, cream or salmon variety. I recommend The Sultan for the exhibitor. Its glistening black-maroon will contrast well with the lighter shades. It is a very vigorous grower, has big blooms, mostly in fours on huge stems, while it seems to have all the qualities of a first-class variety. If a chocolate maroon is preferred I would suggest Warrior, now very well known.

Few will disagree with my choice of Charity (crimson) and Royal Purple for tenth and eleventh places, respectively. Both are good growers, distinct colours and useful for all purposes.

My last choice is Tangerine Improved for the exhibitor. Its colour, so aptly described in the

name, is one of the loveliest shades we have in Sweet Peas. Alas! it is not easy to grow, for it is not very vigorous and requires shading; but when it is grown on a single stem and protected from the sun it will repay a little extra care.

I think I should suggest either Valentine (blush-pink) or Annie Ireland (white, with a Picotee edge of pink), in place of it for garden decoration. The latter is one of the daintiest of Sweet Peas.

For keen competition all varieties should be grown on the "cordon system," but after the shows are over they can be allowed to grow away freely when they will provide plenty of cut flowers, and in a favourable season, finish well above the supports.

NORMAN LAMBERT.

NOTES OF THE WEEK

A RECENT visit to Kew Gardens confirmed a previous impression that, despite the mild winter, many plants are distinctly backward this season. This is particularly the case with alpinists which, even under glass, are far more backward than one would expect. The plants in the Alpine House, in fact, seem more backward than those in the frames, which probably affords an explanation of the phenomenon. A spell—even a short one—of hard weather would have "put the plants to sleep," and they would now be less drowsy!

Primula Winteri Outdoors.—Everyone—at any rate, every lover of choice hardy plants—knows that *Primula Winteri* is hardy and knows also that it does not succeed outdoors! A little colony of plants, which have now had practically twelve months outdoors, is therefore of special interest. These are planted quite under the shade of Sargent's weeping form of the Canadian Hemlock—*Tsuga canadensis Sargentii*—and owing to the umbrella shape of the tree are quite immune from drip. The plants certainly look healthy, not to say robust. No visitor to Kew interested in the plant should fail to look out for them in the rock garden.

Snowdrops.—To most people, even to many keen gardeners, Snowdrops are very welcome harbingers of spring, and of their form and colouring they have quite a clear idea. That there

are quite a number of species and varieties does not occur to one simply because—excluding the rather bloated double ones—they are so much alike. Yet some forms are finer than others and, what is even more important, some are decidedly earlier than others. The beautiful and early *Galanthus Elwesii* is, at any rate, in a good form, admirable, but it needs a little more shelter than the forms of *G. nivalis* or the very closely related *G. Imperati*, which is illustrated and which is extremely beautiful. One of the most distinct of Snowdrops is *G. latifolius*, with foliage almost broad enough for a Tulip.

Box Hill.—We publish on another page an appeal from the Editor of *Country Life* for funds to round off the National Estate at Box Hill. It is essential for the public enjoyment of the land already given that the area now offered by Lord Francis Hope should be saved from the hands of those who would disfigure one of England's most precious beauty spots with unsightly erections, such as are already springing up in the neighbourhood. Box Hill may be looked upon as a National garden—indeed, many gardeners might learn much as to the arrangement of trees, shrubs and plants from a visit there—and we confidently commend to all garden lovers the purchase of this additional area as an entirely worthy object and one of lasting benefit to the community.

THE WIDE-SKIRTED GALANTHUS IMPERATI.

NOTES ON DAFFODILS

A FINE NEW WHITE TRUMPET DAFFODIL.—*Narcissus Everest*, illustrated herewith, was shewn by the Donard Nursery Company of Newcastle, Co. Down, at the Midland Daffodil Society's Show at Birmingham last April, when it gained a unanimous award of merit. It was much commented on, and was in my opinion one of the very finest things at the show. The flower is pure white throughout and is of fine waxy texture, having broad, well formed perianth standing at right angles to the trumpet, which is beautifully finished with a neat flange at the brim; perhaps its most striking feature was its tallness. White trumpets are, unfortunately, rather short-stemmed as a general rule, but I should say that the stem of this variety must have been about 20 ins. in length. It is an early bloomer.

THE NARCISSUS FLY.—I have never had serious trouble with this pest here, as it is probably not so much at home in our rather cold, wet and cloudy climate as in districts that enjoy a considerably greater amount of sunshine; however, I have usually had a few odd bulbs destroyed by it, and a method of dealing with it which I have just tried with apparent success may be of interest. It has been my practice to go over the Daffodil-beds any time between November and the end of January, when top growth is well started, very carefully uncovering the tops of all the bulbs row by row with the assistance of a boy, the boy working on one side of the bed and myself on the other simultaneously. When the bulbs are thus uncovered it is quite easy with a very little practice or experience to detect any bulb or nose of a bulb which has not sent up its strong white shoot or whose growth is in any way defective or sickly-looking so as to give rise to suspicion. Where the growth has failed to come from a nose, it will almost always be found if the bulb or offset is taken up and split open that it contains a Merodon grub. I have found them in all stages of development, from such a small size that some care is required to find them up to full grown. Each row of bulbs is, of course, covered again after examination before proceeding to the next. By this method I think that very few, if any, grub-infested bulbs escape detection, and it must certainly be very effective in reducing the number of flies provided that they have no other adjacent breeding-ground. In the winter of 1921-22 following on the hot, dry summer of 1921, which was doubtless exceptionally favourable to the fly, we found a greater number of grubs than usual, so in addition to the above method of

attack we adopted a plan of defence as follows: Throughout the growing season the soil is kept constantly cultivated between the rows of bulbs; this was done very thoroughly, with frequent forkings last spring; and just when the flowers were over, the weather being dry at the time, we gave

NEW WHITE DAFFODIL EVEREST.

the beds a final thorough and fairly deep forking, but not deep enough to disturb the roots. After this the loose soil was drawn up with the hands into little ridges as high as possible against the rows of plants and carefully packed as closely as possible around the foliage to prevent the fly crawling down the holes left by withering stems and foliage to the bulbs, which are thus, for the time being, more deeply buried than usual. This operation is very simple, and can be carried out a good deal more quickly than might be supposed when the soil is dry. When the foliage had died down it was raked off, the little ridges levelled, and the beds again forked over. The frequent forking and disturbing of the surface soil is in itself undoubtedly a safeguard, as any stray egg or minute newly hatched grub is likely to be put beyond reach of its objective thereby.

The result of our efforts has been most satisfactory, for, when we began our usual hunt for grubs this winter by uncovering the bulbs, about a month or six weeks ago, we could not find a single grub-infested bulb, although large numbers were carefully searched. Last season was, doubtless, less favourable to the propagation of the fly than the preceding one, but the complete absence of grubs can scarcely be attributed to that here, as I found

two in a small bed which I fancy had been overlooked when earthing up in another garden where I grow some of my Daffodils about half a mile from here. Whether our success was mainly due to our having exterminated most of the flies in the grub stage by the bulb to bulb search in the winter of 1921-22 or to the defensive method of carefully forking the surface soil and well earthing up the foliage last spring it is difficult to say; but I am rather inclined to give most credit to the latter operation—which has the merit of being much more easily and quickly done—as, when the former only had been carried out in previous seasons, grubs were never completely absent, as they appear to be this winter.

Broughshane, Co. Antrim. GUY L. WILSON.

A ROCK GARDEN INDEED

SO many beauties of nature have been swamped by the ever-rising tide of villas and hotels on this sunny coast that it is pleasant to state there is a spot—indeed, a unique one—high up among the rocks under the Crag of Monaco where true taste and the art of the gardener have successfully added to the natural flora and created a *new world*, one may say. To anyone entering this rock-bound area, where the late Prince of Monaco commenced a garden for Cacti and succulents some thirty years ago, the spectacle of tall, columnar and branching Cacti that have now grown to the stature of trees is startling in itself, and the bright red fruits with which they are so plentifully adorned add to the strange effect. That is, however, a mere beginning to the wonders to be found as you advance.

During all these years the late Prince and his excellent gardener, M. Gastaud, have been collecting plants and seeds from Mexico, Peru, the Cape, the Canaries and other far-distant lands and, not content with merely planting them, have been busily engaged in making new hybrids and carefully making selections from the seedlings they have raised. To do justice to it needs another pen than mine, but any account, however inadequate, is better than none. The garden is so high up and so inaccessible till these new roads have been made that it has been but little visited. No doubt the Prince was glad to have a retreat where he could get away from the crowd and feel as if he were travelling in a far-off land! What may happen under the new ruler I do not know, but I sincerely trust it may be kept up, as there is nothing to compare with it in variety and richness. The flowering Aloes and succulents, the weird Cacti, the strange Euphorbias and Senerios must be seen to be appreciated. Perhaps one of the most striking things is the way some of these succulents mimic the growth and general effect of Fir trees or other evergreens. In particular, some of the Phyllocacti, with their upright growth and flat tiers of spreading branches, recall a young Araucaria or some other conifer so closely that at first sight one wonders why such a tree should grow here. The mimicry of some of the Euphorbias is well known, of course; it takes an expert to decide at first sight whether it be Cactus or Spurge till you cut it, when the milky sap tells its own tale. Here, indeed, there are wonders enough for the wisest of men, and the flowering of the Aloes in February will give a blaze of colour as great as any bed of Geranium or Tritoma can give in August in northern gardens; while the variety in stature and mode of growth are a delight to the eye of the artist and the discerning

gardener. Cactus, *Cereus*, *Phyllocactus*, *Echinocactus*, *Kleinia*, *Mamillaria*, *Mesembryanthemum*, *Sedum*, *Senecio* and many another genus or species are all there with their hybrids in bewildering variety. As a rule one may say each is more thorny than its neighbour and unassailable to the toughest customer in the desert from which they spring. I should doubt if the horny hoof of even a mule could succeed in breaking through the array of spines that protect the juicy globes of these desert plants that store up sap where no water can be found. To sit down hastily in this garden would be a disaster, so the Prince has kindly provided seats at intervals in the ascent. We have all heard of "stony griets," but here there are "thorny joys" as well, a combination rarely met with and one that will live long in the memory of

Nice,

F. H. WOODALL.

BULBS FOR SPRING PLANTING

MUCH that is really essential in the flower garden during the late summer and autumn is supplied by bulbous and tuberous-rooted plants that may be planted in early spring. Among these, *Gladioli* are worthy of first mention, to be closely followed by the newer *Montbretias*. The Cape Hyacinth, *Galtonia candicans*, is quite distinct and handsome withal; while for Lilies—particularly the *speciosum* group, no praise is too high. Other species of a dwarfier nature there are, but on this occasion our concern is for the taller and more gorgeous of these, which should be planted towards the end of March and beginning of April. The modern *Gladioli* are stately plants, much superior in every way to the majority of those in commerce throughout the greater part of the last century. They have been kept up with the times by those who are alive to their possibilities. By careful breeding and selection the weak-habited, washed-out coloured varieties have been gradually removed, so that at the present time there is hardly a named sort in the catalogue of a reputable firm that is not worthy of its place in any garden. Some of these have 3 ft. long flower-spikes, as much as half of which is closely studded with vivid-coloured flowers which open in their turn from the base upwards, a process taking up considerable time, thereby enhancing their value not only in the garden, but for cutting. Scarlet, pink, yellow and blue are all now available, and it would be difficult to imagine a garden where their free use would not greatly enhance its early autumn charm. In conjunction with perennial *Phloxes*, with many annuals and carpeting plants, or in combination with the white-bellied, *Galtonia candicans*, already alluded to, it is only a question of blending or contrasting their colours as individual taste may prefer, in order to obtain beds and borders rich in beauty with the least possible amount of trouble. To fill in the dull spots in the herbaceous border, which cannot be avoided in spring and early summer flowering plants are employed. *Gladioli* are invaluable. They may be planted, assuming the soil to be in fair condition, without the necessity for much disturbance of the plants near, and in colonies of sixes or nines, according to the width of the border. Nothing that is now available for planting in a dormant state is more reliable or more beautiful.

No less remarkable has been the advance during the last decade or so of *Montbretias*. Nearly

every lover of hardy flowers is familiar with the perennial occupant of old flower borders, *Meibomia* and its varieties, with their small spikes of orange-coloured flowers which invariably failed to open out fully, as if afraid of too close inspection. That they were permitted to reign in many cases was because their requirements were of a simple order, and they were hardy in the extreme. It is perhaps not too much to say of the newer hybrids that, both in habit of growth and flowers, they are *Gladioli* in miniature; but they are much more artistic, since the spikes are lighter and, though branching, are not heavy. In accordance with all this is the setting of the flowers—they do not overcrowd. Reference has already been made to the shortcomings of the flowers of the old species, but in the new hybrids these have given place to a fully expanding type, 2 ins. to 4 ins. across. Some of them are quite flat, and with age have a tendency to recurve, thus revealing the richness of their markings in the best possible manner. *Star of the East*, *Germania*, *Prometheus* and *George Davidson* are but a few, typical of many, possessing the foregoing qualities at a reasonable price, and which justly entitles them to a place among the choicest plants for garden decoration while for cutting they have few equals. In order to enable these to give of their best it is most essential to bear in mind that they are vigorous growers and bear no comparison to the retiring disposition of the old species. They must be liberally treated in the matter of

soil preparation, and on no account allowed to suffer through lack of moisture at their roots. Of equal importance is it that they should be lifted and stored during the winter in a similar manner to *Gladioli*.

With a host of Lilies to select from the reason for preference being given to the *speciosum* group is that there is less likelihood of them proving disappointing, since they are of the easiest cultivation, having none of the likes and dislikes of soil, situation and locality of some of those generally recognised as garden varieties. All the popular sorts comprising this fascinating group are now being imported freely and the bulbs are of good quality. A great many find their way into pots for greenhouse decoration, but in many parts of the garden they are welcome additions to the ranks of early autumn flowerers. In common with other Lilies they revel in a light sandy loam, and time spent in preparing stations for them is amply repaid. They are stem rooting, and the bulbs should be planted rather deep in consequence and be covered with the lightest soil.

In *Galtonia* or *Hyacinthus candicans*, we have one of the best bulbs for present planting. In the mass their towering white spikes, over 4 ft. in height, are very effective. For grouping among early-flowering shrubs or at the back of the herbaceous border few things are more useful. As with Lilies, the bulbs should rest on and be surrounded with sandy soil, and they should be put some 3 ins. below the surface. J. T.

THE SNOWFLAKES

BEST of all the spring-flowering Snowflakes—if one excepts the charming *Leucojum nicaense* (illustrated in our last issue), which is too particular in its requirements for outdoor culture in Britain—is the plant illustrated below, which, botanically a variety of *L. vernum*, is, from a garden standpoint, entirely distinct. The blossoms are a beautiful warm creamy white, very welcome at this season when, though vegetation is awakening, it is still far from wakeful. Each flower segment is attractively tipped with gold. By comparison with this treasure the typical Spring Snowflake,

L. vernum, is a coarse plant, yet taken on its own merits it is a very desirable plant, bolder and showier than the Snowdrops and quite as early to flower. It takes a year or so to establish imported bulbs, but, once established, it is an easy doer in light soil, not deficient of humus, and increases rapidly. It succeeds quite well in the border in sunny woodland, but is perhaps seen to best advantage on a sunny ledge in the rock garden.

The so-called Summer Snowflake, which actually flowers in late spring, bears clusters of snowdrop-like blossoms on stems up to 2 ft. tall. It is an interesting-looking, though old-fashioned plant,

A BEAUTIFUL FORM OF THE SPRING SNOWFLAKE—*LEUCOJUM VERNUM CARPATICUM*.

CORRESPONDENCE

SPOTTINESS IN PLANTING.

IN your issue of January 27 there is an illustration of a water garden bearing underneath the words "admirably planned and planted." I wonder if other readers besides myself felt that there was something wrong with the picture, that the words were not perfectly appropriate. There is so much to be learnt from looking at garden pictures. I have been looking carefully at this one and asking myself why it seemed, to my judgment, unsatisfactory. Do not you think the planting needs simplifying and broadening? Look, for instance, at that one plume of—is it *Stenanthium*?—on the right. If the plant had been massed it would have looked right enough, as it is it looks like a botanical specimen just in the sort of place where such specimens look most out of place. In front of this is a clump of some half a dozen roots of a Bearded Iris. Would not it have been far better to have had a much larger planting of a water-loving Iris such as *sibirica*, *Emperor* or *Snow Queen* or *Kemperi Morning Mists*? The single clump of *Funkia* (*Sieboldi*?) on the bank opposite would look fine if better placed, but here seems merely an unrelated "spot plant." The big *Spiraea arifolia* is splendid, of course, and so is the dark background; but, apart from these features, much of the planting seems (to judge merely from a photograph) to lack something of the breadth that streamside planting generally calls for. I send you this note not, of course, as a criticism of the delightful illustrations in *THE GARDEN*, but simply as an amateur's analysis of one picture. Some other reader, perhaps, will be sufficiently amused to turn up the back number and see if he agrees with my comment. I was so glad to see in the same number what you say about the different qualities of white in border flowers, and about the unpleasant effect of overlarge masses of cold white. A few more warm whites occur to me as perhaps worth adding to your list: *Camassia Leichtlinii alba* (excellent with single scarlet *Paeonies*), *Hyacinthus candicans*, of course, and *Yucca filamentosa flaccida*. A long-flowering little shrub useful in the border, is Farrer's white natural hybrid of *Potentilla fruticosa*. Poppy Perry's White is beautiful in colour.—A PAINTER.

[Without seeing the garden from which a picture is taken, one is at some disadvantage in criticising the planting. To the Editor the little glade shewn seems too small for very large clumps of plants. Probably the plants shewn are outlines of larger groupings in the background. In which case their presence needs little justification, yet on looking carefully at the picture again probably "admirably planned" would be a more fitting title to the picture than the one given. The arrangement of the stones in the bed of the little stream is certainly much above the average.—Ed.]

THE MILD WINTER.

THIS is not by any means a warm district, but this is an exceptional winter here as elsewhere. I enclose a spray of parsley-leaved Blackberry growing on a wall with an eastern aspect which has been flowering for several weeks, and has even managed to set some fruit.—W. H. ST. QUINTIN, *Scampston Hall, Yorks.*

[The spray of parsley-leaved Blackberry, *Rubus laciniatus*, bore fast ripening fruits, and had obviously been quite recently in flower.—Ed.]

THE GOLDEN THYME.

THE Golden Thyme referred to by Mr. Clarence Elliott on page 25 was not found wild on the Welsh hills. In October, 1905 or 1906, I

saw a golden spray coming out of the crown of an Encrusted Saxifrage which Mr. Wolley Dod had given me shortly before his death. The wild Thyme referred to by Mr. Clarence Elliott was found on the top of Snowdon in 1891. It flowers from two to three weeks earlier than any other variety.—E. CHARLES BUXTON, *Bellis-y-Cood.*

IRIS RETICULATA UNDER GLASS.

I SHOULD fancy that most readers of *THE GARDEN* know *Iris reticulata* as one of the most welcome—as it is certainly one of the most beautiful—of early-flowering bulbs. I have been successful in establishing it both in the rock garden and in short grass. Properly arranged it is exceedingly charming in the turf of the wild garden, which sometimes borders, happily enough, the rockery. The enclosed picture shews this plant put to a new use. If good enough for reproduction it would, I think, interest many readers. Like most Irises, it resents forcing, but even if grown in an entirely cold house the blossoms appear under glass early in the New Year.—G. HARVEY.

[The photograph mentioned, of a pan of *Iris reticulata* was hardly suitable for reproduction. The picture accompanying the note is of a bowl of these beautiful flowers exhibited at the mid-January meeting by Messrs. Sutton and Sons. The plant is neat enough to associate with the choicest of alpinists under glass.—Ed.]

THE VALERIAN AND SELF-SOWN SEEDLINGS.

I WAS very pleased to see your note on the above plant (*THE GARDEN*, December 23, 1922, page 652). My business engagements have taken me away from home very often during the past two seasons, consequently one part of my garden—the rock border that claims my personal attention—has been neglected and allowed to run wild. To-day this rock border is a riot of self-sown seedlings and young plants of trees, such as *Sycamore*, *Thorn* and innumerable common weeds. There the beautiful *Valerian*—one of my favourite plants, either wild or cultivated—has become a weed and a pest, with a special liking to establish its numerous off-spring among my beds of Mossy Saxifrages and Sedums, while groups of alpine *Dianthus* and *Aubrietia* are their special abiding places.

Among the Flag Irises they have also found a home. This *Valerian* will certainly soon fill a garden if left to seed. The reminder in the note referred to—"the easiness of its cultivation makes it a most desirable town garden plant, so long as it is not permitted to seed"—should therefore be borne in mind. I grow this plant upon a raised border, where I find a difficulty in establishing most plants, the soil being little more than sand, with very sharp drainage. The

Valerian is just the plant for such dry and hungry soil. The natural habitat of the *Valerian* is among limestone formations. In the sowing of seed great care should be exercised in the selection of varieties. When I commenced to grow the *Valerian*, seed was purchased from a first class firm making a speciality of an improved coloured form. My disappointment was great when viewing this plant growing wild by the tens of thousands, one colour form of the wilding throwing my special plants quite into the background. In North Wales there are three distinct colours—a very vivid and distinctive ruby red, crimson and pink. The latter colours should be avoided for garden

A BOWL OF THE DAINTY IRIS RETICULATA.

decoration. There is also a very beautiful white variety growing in the Llandudno district.—GRANITICUS.

TRAPPING VERMIN.

MOST of the methods advised by your contributors of notes on above to *THE GARDEN* recently are, so far as tried by myself, as disastrous to birds as the vermin they are set to destroy. Usually the first victim in the "break-back" is the friendly robin which follows one's doings in the garden very attentively. The hedge sparrow that early in the year gives forth its not unpleasing melody is also a not unusual victim and, of course, the beautiful and entertaining tits, which probably do considerably more good than harm in the majority of our gardens; I do not think there is any question that they mainly subsist on insects, larvæ and pupæ, which they are constantly ranging the trees and shrubs for. The "brick" trap advised and illustrated would probably be as disastrous to bird life as the "break-back." Our gardens would lose one of its great attractions if it were not a sanctuary for bird life, and in most gardens the damage they do is compensated for by the pleasure and companionship that is felt towards them, at any rate by some, and the beautiful music they generously provide, especially in the springtime of the year. Mice trouble me considerably at times, especially playing havoc with *Crocus* and other bulbs, and also nibbling back the *Dianthus*, alpine *Phlox* and other similar plants, which they at times

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

carry away wholesale and store in their temporary domicile. In trapping I usually use the old-fashioned three-hole wood mouse trap which has wire spring nooses tied down with thread and which is baited with cheese, nuts, aniseed, etc., to reach which the mice have to nibble through the thread, which releases the spring. It does its work quite as effectively as the "break-back," and I have never had a bird of any kind trapped in it. I have had three mice trapped at one time and often two. Sometimes the bait is extracted without the thread being cut through, probably by the "pigny shrew," a lovely, quaint little animal which can possibly push its way through between the threads. I have often had the bait taken off the "break-back" trap (set inside) without releasing the trigger. Some of the mice seem almost to suck the bait off. Recently I noticed some Tulip (species) seeds which were just coming through, were being tampered with by something, and set three traps in the frame, the whole of them on occasion having the bait taken without going off, but during the first week of this year I took two long-tailed field mice, two field voles and a pigny shrew out. I have also tried the "Colm Pullinger" trap advised in THE GARDEN some time ago, but, unfortunately, got one that was not properly balanced and, of course, did no good with it. It was altered for me, but the balance still does not seem to be right, and I have only had one mouse in it. The drawback to this trap is that the mice are caught alive and either die a lingering death or it alive when the trap is examined have to be drowned.—T. A. LOFTHOUSE.

CHRYSANTHEMUM TOKIO.

AS an old "Mummer" I was much interested in the pars. by Mr. E. H. Woodall and my old and esteemed friend, Mr. Harman Payne, *re* the variety Tokio. I am pleased at times to read and to feel that Mr. Harman Payne's enthusiasm and unbounded interest in the Chrysanthemum has not waned with years. He has carried on correspondence and kept up *L'Entente Cordiale* with our French neighbours for years, much to the advantage and benefit of many of us on this side of the Channel who have never been able to visit the French exhibitions and see their methods of staging. When I read Mr. Woodall's note, and subsequently Mr. Harman Payne's, describing the variety Tokio as a good pink, I felt that there was either a mistake or that there were two varieties in cultivation under the same name. I grew and used Tokio some thirty years or more ago in my exhibition groups, on account of its bright red colour and dwarf habit, for the front plants. Bright colours were not so plentiful then. Mons. Henri Jacotot was then one of the best and largest, as well as the brightest. Later on we had Cullingford, very effective for colour. Perhaps Mr. Payne may enlighten us on the subject.—C. ORCHARD, *Bembridge, Isle of Wight.*

FORTHCOMING EVENTS.

February 12. United Horticultural Benefit and Provident Society's Meeting. Lecture at the University College, Gower Street, London, W.C.1, at 5 p.m., by Mr. H. C. Thornton, B.A., on "Conditions Affecting Bacterial Activities in the Soil—Activities Connected with the Intake of Protein Building Materials."

February 13. Royal Horticultural Society's Fortnightly Meeting and Annual General Meeting.

February 14. Lecture at the University College, London, W.C.1, at 5 p.m., by Mr. D. W. Cutler, M.A., on "Protozoa of the Soil."

Herbs. Perhaps the most popular herb is Mint, and to obtain this of the best quality a new bed should be made every year. It is increased by division and now is a good time to replant. Parsley is raised from seeds and the first sowing can be made during this month and another in July. Sow the seeds thinly and thin out the plants to 6 ins. Sage can also be raised from seeds, but preference should be given to cuttings taken in the autumn. The common Thyme may be increased by division at this season, or raised from seeds, which may be sown any time during the spring months. There are a number of other herbs in cultivation, most of which can be raised from seeds.

Broad Beans.—If the soil is in a fit condition the main crop of this useful vegetable should be sown in double lines 2 ft. apart and 6 ins. apart in the rows. Beans enjoy a strong soil, but good crops can be obtained from any ordinary garden. The Longpod varieties are usually grown by the amateur, but the Windsor kinds should certainly be given a trial.

Parsnips.—Whenever possible Parsnips are sown about this time, but no anxiety need be felt if such is deferred for a few weeks. The seeds should be sown thinly in lines 15 ins. apart, lightly cover the seeds and then draw a wooden rake over the bed, but this must be done in the same direction as the rows. Parsnips should be given a deeply dug piece of ground and a patch that was manured for the previous crop. Use the hoe directly the seedlings appear and thin out 1 ft. apart. Hollow Crown and Student are both reliable varieties.

The Flower Garden.

The Frame Ground should always be kept neat and tidy and the plants in cold frames must be looked over for weeds and decayed foliage, while the soil may be stirred lightly with a pointed stick. Viola cuttings should have their tops pinched out and cuttings of various shrubs, if well rooted, can be transferred to nursery beds. Rock garden plants such as Saxifrages, Thymes and Androsaces, if propagated last August, will be ready for their permanent quarters, but it will be necessary to well harden them by removing the lights both night and day.

Salvia patens.—Among blue-flowered bedding plants *S. patens* occupies a high position and the old plants ought now to be introduced to a warm greenhouse to start them into growth. Large examples can be divided into several pieces and potted up, while sufficient cuttings should be inserted for bedding purposes. This delightful Sage can also be raised from seeds.

Dahlias.—Since the advent of the Peony-flowered and Single varieties, Dahlias have been extensively employed for bedding purposes and few plants are more effective for large isolated beds. The old stools should now be placed in a little heat where they will soon produce a quantity of cuttings. These will readily form roots if sandy soil is used, and the pots of cuttings are arranged in a close propagating frame. Cooler treatment should be the rule directly roots are formed and each cutting must be given a separate existence by potting it off in a mixture of loam and leaf-mould.

Fruits Under Glass.

Peaches and Nectarines.—In most instances far more fruits set than are required for a crop, so it will be necessary to begin thinning them at an early stage. This must be done gradually and the same remark applies to disbudding of the shoots. When disbudding a thought must be given to the future welfare of the tree, remembering that the growths retained now will form the fruiting wood next year. All foretigh shoots should be removed, and care must be taken to see that the base of the tree and the main branches are well supplied with new growths. The shoots that were tied in this season will produce a number of growths and when disbudding the basal one must be preserved, also the terminal shoot and three others equal distances apart. A fortnight or so later two more growths may be removed. Disbudding can commence when the shoots are about half an inch in length. A watch should be kept for aphids for they do irreparable damage in a short time. The house may be lightly vaporised, or the trees syringed with a weak solution of any reliable insecticide.

Cucumbers.—Proceed to transfer the plants to their fruiting stations before the roots become starved. A low house is essential and the vines

should be tied to wires placed about 15 ins. from the root glass. A peck of fibrous loam should be set in position for each plant, but this must be thoroughly warmed before planting. Growth will be fairly rapid in a moist temperature of 65° to 70°, and each lateral must be stopped just beyond a fruit. When the roots appear through the soil add more loam and rotten manure and keep the plants well supplied with moisture. Warm water should be used both for syringing and watering purposes.

The Hardy Fruit Garden.

Autumn-fruiting Raspberries.—Where these are appreciated the Hailsham should be given a trial. All the canes should be cut down to their base and when new ones appear they must be moderately thinned.

T. W. BRISCOE,

(Gardener to W. R. Lysaght, Esq.)

Castleford, Chesham, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Peas. Weather permitting, an early sowing of Peas may be made. It will still be advisable, however, to select the warmest site available, and the drill should be partly filled up with some fine, rather dry soil. Precautions should also be taken against damage by mice or rats.

Broad Beans.—A sowing should now be made for early supplies, and the quick-maturing Early Mazagan is suitable for this sowing. Two feet between the drills is sufficient for this variety.

Rhubarb.—This is a suitable time for making new plantations. The plant being a gross feeder, it requires liberal cultivation. Trench or double dig the quarter, working in a good supply of organic manure with each spit. When the soil has settled a little, plant single or double crowns about 4 ft. apart each way. An alternative system is to excavate pits from 30 ins. to 30 ins. in diameter and 30 ins. deep, and incorporate a good supply of manure with the soil as the pits are being filled in; distance apart as above.

Fruit Under Glass.

Peaches which have set their fruit should be vigorously syringed to rid the trees of the decaying flowers. The trees should now be syringed every afternoon and the pathways sprinkled with water twice daily. The trees must not be allowed to get dry at the root. Ventilate on all favourable occasions and maintain a night temperature of 50° or thereabouts.

Strawberries.—Plants in flower should be fertilised by means of a camel's hair brush or a rabbit's tail. A rather dry, buoyant atmosphere is desirable at this stage. Plants which are swelling their fruits should receive the assistance of some approved fertiliser, such as Clay's or Icthemio guano, rather weak and frequent doses being preferable to strong doses given at long intervals.

The Flower Garden.

Antirrhinums.—For planting in masses the Antirrhinum is hard to beat. Seeds should be sown now to furnish plants fit for planting in the first week in May. Sow in boxes as for the general run of half-hardy annuals. Of the three classes, tall, medium and Tom Thumb, the medium varieties are the most useful.

Dahlias.—Cuttings should be taken as soon as they can be had from 2 ins. to 3 ins. long. Insert these in an ordinary propagating bed, where they will soon root. When sufficient cuttings have been obtained the old tubers can be transferred to a cool structure with a view to their being planted out in the herbaceous border or elsewhere.

Spring Bedding Plants.—Take advantage of dry, open weather to stir the soil with a small hoe between Wallflowers, Forget-me-nots and Daisies. If mice are tampering with Tulips, they should be trapped or poisoned.

The Hardy Fruit Garden.

Strawberries.—Where plantlets have been laid in in nursery lines for spring planting preparations should be made for planting them out. The quarter, if trenched or dug in autumn, should now only require to be forked over when weather permits. Run the Dutch hoe through between Strawberries planted in the autumn.

The Pleasure Grounds.

Lawns.—Any turfing which has to be done should be dealt with as soon as possible. Happily this work can be taken in hand when the weather forbids many other jobs being dealt with.

CHOICE IRIS from CHISLEHURST

If you are contemplating either adding to your Iris garden or forming a collection of Iris, you cannot be without the following varieties. Order them now for Spring planting:

Alcazar (Vilmorin).—S. bright deep aniline blue, F. rich deep velvety violet purple, with a prominent yellow beard. Very tall.

Ambassadeur (Vilmorin).—Flowers large, with smoky reddish violet standards, and falls dark velvety reddish violet. Beard yellow. Height 4ft. A.M., R.H.S.

Ambigu (Vilmorin).—S. clear smoky red, and falls a velvety reddish brown. Height 2½ft.

Asia (Yeld).—A.M., R.H.S. Pale lavender standards suffused yellow at the base, falls light purple violet, paler at the edges, heavily reticulated at the haft. Bright yellow beard. Height 4-4½ft.

Crepuscle (Vilmorin).—A fine violet blue self, with very large flowers. Very free flowering.

Dejazet (Vilmorin).—Of distinct and beautiful colouring. Dusky rose orange, and F. clear reddish violet. Robust grower, of medium height.

Eldorado (Vilmorin).—S. yellowish bronze, shaded beautifully with heliotrope, falls bright petunia violet, tinged with bronze yellow at the haft, and a prominent yellow beard.

Ed. Michel (Vilmorin).—A.M., R.H.S. Of imposing appearance of a distinct reddish petunia violet colour, with falls slightly deeper than the standards.

Halo (Yeld).—An exceedingly fine Iris, with large and good quality flowers. S. light violet, F. bluish violet.

Lord of June (Yeld).—A very strong grower with massive flowers. S. palest lavender blue, F. deep rich aniline blue. A.M., R.H.S. Height 2½-3ft.

Lohengrin (G. & K.).—S. pure light aniline blue, F. bright pale violet. Very beautiful. A.M., R.H.S. Height 2½-3ft.

Mrs. Neubronner (Ware).—Uniform shade of rich golden yellow, one of the finest yellows. Height 2ft.

Oriflamme (Vilmorin).—S. brilliant pure blue, F. deeper blue purple. Height 2½ft.

Opera (Vilmorin).—Magnificent variety. S. rich pansy violet, shaded to brownish violet at base; F. a rich velvety violet purple. Height 2½ft.

Prospero (Yeld).—A.M., R.H.S. S. pale lavender, F. rich deep violet purple, slightly paler at margins. One of the best.

Pallida Celeste.—Pale silvery blue standards, and lavender falls. Very beautiful.

Richard II (Dykes).—Standards, pure white, falls deep violet conspicuously margined white. Most prolific. Height 1½-2ft.

Queen of May.—A pallida form, rosy pink.

All above are sterling value, and should be included in all collections.

All coarse patches of grass should be removed and be replaced by suitable turf. Any depressions should have the turf thrown back and the depression levelled up with soil that is not too rich.

Walks requiring a fresh supply of gravel should have attention now. Old walks can be freshened up by loosening the surface to a depth of a few inches and sifting the earthy portion into a barrow to be wheeled away, only the clean gravel being retained.

CHARLES COMFORT

(Formerly Head-gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Salvia azurea var. grandiflora (syn. *S. Pitcheri*) is a beautiful blue-flowered plant which is hardy in the south, but flowers very late, often getting damaged by late frosts. It is, however, an excellent plant for the cool conservatory. It is easily raised from seed sown at this time, or from cuttings, which may now readily be rooted in a case in a cool house. In fact this plant may be given exactly the same treatment as *Chrysanthemums*. Good specimens can be grown in 10-in. or 12-in. pots, and during the summer they should be stood out on an ash bed. These plants require strict attention as regards watering and feeding for, if neglected in this respect, they are apt to lose their bottom leaves and also suffer from attacks of red spider.

Salvia uliginosa is another late-flowering blue species, also worth growing in the same way. It is a strong rooting species and requires very generous treatment. Here at Kew it is not over hardy and requires some dry leaves or ashes over the crown to keep it safe.

Salvia Greggii is a very pretty red-flowered species, useful for the greenhouse and conservatory during late summer and autumn. It is a shrubby plant and makes neat specimens in 6-in. pots. It is easily propagated at this time by means of cuttings, which root readily in a case in a cool house. During the summer it should be stood outdoors in cold frames or on a bed of ashes in the open.

Fuchsias raised from cuttings last September and kept growing steadily on during the winter should now be potted on, giving them a rich compost, as it is essential that they make free and rapid growth. If given generous treatment they should make good specimens during the coming summer. Old specimen Fuchsias should now be got out and pruned, at the same time cleaning them; this is very necessary if they were attacked with mealy bug last season, and they are very subject to attack by this pest. If well watered and stood in a warm greenhouse, where they can be syringed several times a day, these plants will soon start into growth, when they may be turned out of their pots and a portion of the old soil removed. They should then be repotted into the same sized pots. They should be kept close and sprayed over with the syringe several times a day until they are growing strongly, when they may be given more air, regulating this according to the outdoor conditions. Where it is desired to increase the stock, plants should be started into growth in a warm house. The young shoots when pins, in length root very readily in a close case. Where they can be planted out Fuchsias are ideal plants for training on rafters and pillars in the conservatory and in such positions they grow freely and flower with wonderful profusion right through the summer and autumn. Many of them are also excellent for filling baskets; for this purpose varieties with a natural drooping habit should be selected. Mrs. Rundle and Mrs. Roberts are good examples of this type. Cloth of Gold is a slender, drooping variety with golden foliage.

Malmaison Carnations wintered in 4-in. pots should now be ready for a shift into 6-in. pots. The compost should consist of a good medium loam and unless it is on the heavy side is better without the addition of leaf soil. Lime in some form is necessary for all Carnations and where it can be procured old mortar rubble may take the place of sand in the compost. A 6-in. potful of fine bone meal and a dusting of soot should be added to every bushel of soil. If fresh lime is used in the compost do not add soot. Firm potting is essential and the plants should be kept close for a few days until they get a hold of the fresh compost. Specimen plants should now be growing away and will require more water at the root. There will now be less danger of rust. The only preventive and cure for this is dryness during the dull months; not a drop of water on the foliage and no more at the root than will keep them from shrivelling.

All the spraying nostrums only aggravate the evil, as a certain amount of moisture is essential for the growth and spread of the rust. Perpetual-flowering Carnations may still be propagated according to requirements, while earlier rooted batches should be potted off. Keep a strict outlook for aphids on plants nearing the flowering stage. Occasional light fumigations should be given as a preventive.

J. COCHRAN.

Royal Botanic Gardens, Kew.

The Amenities of the National Estate at Box Hill

We have received from the Editor of "*Country Life*" the following:

ABOUT a year ago attention was called, in the Press, to the fact that Box Hill was in danger, a very large adjoining portion being for sale and described as "ripe for development." The Nation's property there, after Miss Warburg's gift last year, consists of Box Hill and half a mile of the main ridge to the eastwards, together with the northerly spur, the valley up which the road runs, and the next spur to the east, which forms one side of the most beautiful part of the whole place, "Happy Valley." Thus the Nation's estate of 300 acres is of an "L" shape, very narrow on the main ridge.

It is the area, 248 acres in all, immediately north of this narrow strip, which is now offered for sale by Lord Francis Hope. It consists of open woods, a bracken-clothed plateau with gorgeous views over "Little Switzerland," and the line of the downs westwards, and—most important—forms the eastern side of "Happy Valley." Its acquisition would convert the Nation's property into a compact rectangle. Lord Francis Hope has intimated that, in the event of the land being sold to the Nation, he would put forward to his Trustees a price of £5,000 for the land, plus £2,000 for the timber or, alternatively, £5,000 net, provided he is allowed to cut timber not exceeding £2,000 in value before sale. This latter, of course, is most undesirable. The offer is a generous one for it works out, with the timber, at £28 per acre, as compared with £50 per acre paid by the late Leopold Salomons for the original gift of Box Hill proper.

The articles and correspondence which appeared last year in the Press provoked an offer as generous from a reader of *Country Life* living in Rio de Janeiro, who wrote as follows:

"I have carefully studied the matter and think it is a good opportunity for anyone wishing to do something *pro bono publico*, and therefore am very glad to send you the enclosed draft of £1,000 towards the purchase of the land (with the conditions I will mention later).

"In buying land for the public one has to be careful that private interests do not reap as much or more benefit than the public, but the present estate, lying alongside a piece already public property, gives the public not only its own actual area, but adds a value to what the public already owns. This is a great point."

(We would add that it does more; it prevents the deterioration of what the public now holds, through the sale of the land for what proves to be the most vulgar form of development.)

"Now I am not a wealthy man; I work very hard for every thousand pounds I earn, but I do not pay English taxation, and I want to help decent things to be done in England.

"So I send you the thousand pounds with the following obligations and conditions:

"(a) That the purchase be completed before September 30th, 1923.

(b) That in addition to this £1,000 herewith,

I will subscribe the last £1,000 required.

This should encourage other subscribers.

"(c) That if the money be not subscribed by the date mentioned above, you return to me the thousand pounds and I am absolved from further responsibility.

"I think it very good of you to be working up this purchase. I do not want my name to figure, you can use my initials.

Yours very truly,

H. H. C."

The Box Hill Committee have voted £1,000, but we must appeal to England for the balance—£4,000, to those who, like our friend in South America, wish to see decent things done in England. *Country Life* will give an initial £250 on condition that three donations of a like sum are forthcoming.

The danger is a very real one. Where land has already been developed, as along the road to Box Hill from Walton, it is horribly disfigured by ruined woods, and bungalows of the meanest sort. The oaks on the land under consideration have already been marked for felling and unless the money can be secured, the beauty of the Box Hill woods will be greatly diminished.

We hope that you will permit us to make use of your columns in order to appeal to your readers for subscriptions, which will be very gratefully received if addressed to: "The Box Hill Fund," 20, Tavistock Street, Covent Garden, W.C.2.

(Signed) P. ANDERSON GRAHAM.

ANSWERS TO CORRESPONDENTS

QUESTION AND ANSWERS.—All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant.

THE ROSE GARDEN.

YELLOW ROSES FOR A CIRCULAR BED (S. C.).—The varieties named by our correspondent (viz., *Golden Ophelia*, *Benedicte Sequin*, *Lady Hillington* and *Emily Gray*), are quite suitable for the purpose, but we prefer *Golden Emblem* to *Benedicte Sequin* as the flowers are a truer yellow. There is a terra-cotta shading in the blooms of *Benedicte Sequin*. *Golden Ophelia* is vigorous and, with good treatment, makes a fine bedding Rose. *Emily Gray* would form a suitable weeping standard and the whole combination a very charming bed.

TREES AND SHRUBS.

AUCUBAS ATTACKED (W. T. B., I. of W.).—The Aucubas are attacked by a scale insect called *Aspidiotus loderae*. This species is extremely uncommon outdoors, though it sometimes occurs in greenhouses. The best treatment will be spraying with nicotine-soap wash made by mixing 3oz. nicotine, 4lb. soft soap, 40 gallons water, or with paraffin emulsion at summer strength.

BEECH AND HORNBEAM (Constant Reader, I. of W.).—The trunk of the Beech is smooth, whereas that of the Hornbeam is commonly rugged or fluted. The habit of the former is open and branching, and of the latter closer and more elegant. Beech leaves are coarsely toothed or have unevenly undulated margins, whereas those of the Hornbeam have a much toothed edging. Again, the Beech has six or seven pairs of leaf veins, whereas the Hornbeam has ten to thirteen pairs, much more closely arranged. The Beech fruit consists of triangular nuts enclosed in a husk; that of the Hornbeam is a ribbed nut at the base of the bract. Beech wood is easily worked, whereas Hornbeam is hard and almost bony in character.

HONEYSUCKLES (C. G. A.).—The nomenclature of the climbing Honeysuckles is very much confused. According to the Kew Hand-list of Trees and Shrubs *Lonicera brachyphylla* and *L. flexuosa* are synonyms for the same plant, which is a variety of *L. japonica*. The flowers should be pale red outside, inside white, changing to yellow with age. It is a vigorous grower and should make a beautiful screen on a wire fence at Torquay. The plant with creamy-white flowers changing to yellow with age is *L. japonica* var. *Halliana*. *L. Heckrottii* in habit is more a loose shrub than of a climbing nature. The flowers are rich pink outside, yellow within, and very freely produced on healthy plants.

LETTERS TO YOUNG SPORTSMEN

ON

HUNTING, ANGLING AND SHOOTING,

BY

Lt.-Col. J. MACKILOP, HORACE G. HUTCHINSON and the Hon. DOUGLAS CAIRNS.

PROFUSELY ILLUSTRATED BY LIONEL EDWARDS
Crown 8vo. 6/- net, by post 6/6.

The Letters appeared originally in the columns of *Country Life*, and are reprinted in book form in response to the requests of a very large number of appreciative readers.

A prospectus of this book will be sent post free on application to the Manager, "COUNTRY LIFE," LTD., 20, Tavistock Street, W.C.2.

TOMATO CULTIVATION: UNDER GLASS

AND OUTDOORS. By R. GIFFARD WOOLLEY. A practical booklet by the Editor of *THE GARDEN*, 9d. net, by post 11d. Published at the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

THE DOG: MAN'S FIRMEST FRIEND.

How to choose and care for him, by A. CROXTON SMITH. A copy of this helpful booklet on the housing, breeding, feeding and care of dogs will be sent post free on receipt of 11d., addressed to The Manager, "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

THE GREENHOUSE.

CHRYSANTHEMUMS ATTACKED (Y. R. R.).—The best treatment for Chrysanthemums attacked by the mining maggot is to spray them with a nicotine wash made of 3oz. of nicotine, 4lb. soft soap, 40 gallons of water.

FRUIT GARDEN.

PEAR BEURRE D'ANJOU (Felsted).—The Pear which our correspondent refers to is, undoubtedly, the one named above. It is large, yellow, with russet suffusion in patches, the flesh is white with an agreeable aroma. In the southern counties it may be grown in bush form, but as the growth is moderate to weakly, even in warm counties this Pear is better trained on a wall. Certainly, in the midlands and more northern districts, wall protection is advisable. It is in season from early November till a little after Christmas. By judicious treatment in gathering and storing the season may, in the midlands, be prolonged till the latter part of January.

MISCELLANEOUS.

CARBIDE WASTE (G. H.).—Carbide waste may safely be used for all purposes for which lime is required in the garden, provided it has been exposed to the air for about six weeks after removal from the generators.

GAS LIME (H. A. G.).—Very old gas lime, if it has been exposed to the air, should be safe to use for mixing with soil. If plants are growing on the heap they will shew whether or not damage is likely to occur from its use. If the material is free from smell it is probably safe to use.

FLOWER FOR IDENTIFICATION (E. W. S., Northumberland).—The flower sent for identification is *Phyllocactus Ackermannii* var. There are many varieties of this species. It is difficult to say what is the matter with the plant without seeing it. Overwatering or cold may have the effect of making it droop or become flabby. All *Phyllocacti* are of easy culture; they prefer a rather dry, warm greenhouse temperature, but will succeed in a colder house when established. The most suitable soil is a light porous loam with some leaf-soil and brick rubble intermixed. The pots should be filled to the extent of one-fourth with broken crocks, and rather small pots in proportion to the size of the plant should be used. When the pots are full of roots an annual top-dressing of soil and dried cow-manure may be given. Watering must be carefully done, and the plants should be kept rather dry in winter.

NAME OF PLANT.—E. M. H.—*Mesembryanthemum nelandens*.

Mr. Henry A. Dreer, 714-716, Chestnut Street, Philadelphia, Pa.—Flower and Vegetable Seeds.

The National Hardy Plant Society.—At the annual general meeting of the Society, held on January 30 last, Mr. Giffard Woolley was unanimously elected Chairman for the coming year, in succession to Mr. Bouskell, now elected President of the Council of the Society. Mr. A. J. Macself of Dactylis, Clifton Park Road, Caversham, Reading, was re-elected Hon. Secretary, and to Mr. Gerald Hillier (20, Tavistock Street, Covent Garden, W.C.2) was given the Assistant Hon. Secretaryship. It was decided that a number of silver and bronze medals should be allotted to horticultural societies for award in 1923 to meritorious exhibits of hardy plants. Societies desirous of obtaining these medals should write to the Hon. Secretary as soon as possible. The accounts shewed a balance in hand at the end of 1922 of about £45, and the Hon. Secretary reported a gratifying increase of membership. So great, he said, had been the flood of correspondence recently from those interested in the doings of the Society that he had been unable to keep pace with it. Suitable arrangements have now been made, however, to ensure that future enquiries have prompt attention. An important item of the Society's programme for 1923 is the periodical issue of a journal detailing the Society's activities and giving information with regard to new or specially noteworthy hardy plants. A large influx of new members is wanted and confidently looked forward to. Everyone interested in hardy plants should enrol himself (or herself)—the subscription is only 7s. 6d.—or if in doubt, write to the Secretary or Assistant Secretary for further particulars.

You can't Dig a Garden—

with good intentions and a hairpin. There has to be some honest spade-work.

You can do your digging and weeding with anybody, but you have your little weakness like the rest of 'em! You like to *look* as though you'd done it. A little perspiration, and good honest dirt thick up to the elbow.

Well, and why not? Just walk about a little where the neighbours can see you, and then—KIT.

KIT soap will clear every atom of dirt, grease, oil, paint or tar out of your hand, and will do it nearly twice as quickly as anything else. It is a nice "spready" sort of soap, so you need only a little. The tin is blue and orange (the handy shape and the handy size), and the lid comes off just when you want it.

Keep a tin in the house for cleaning after "odd jobs."

Price 6d. per Tin.

The "PERFECTOR" ARCH forms an ideal setting for the Rose Garden. The man whose pride is in his Garden will appreciate the simplicity and effectiveness of this design. The construction is light, yet strong enough for a permanency, being specially designed for the cultivation of climbing Roses, Clematis, etc. It is made entirely of OAK and treated with Solignum, size 7 ft. high above ground level, and 3 ft. 4 in. wide inside. Price £1 each. Orders for three or more will be sent Carriage Paid. Cash with order. These can be made wider than 3 ft. 4 in. if required, prices for which will be quoted on application, stating number required.

THE "PERFECTOR" PERGOLA.

This is constructed with the above Arches spaced any distance up to 6 ft. apart. The longitudinal and secondary cross bars to complete the Pergola are supplied in OAK, treated with Solignum, at 1/6 per foot run of Pergola; any lengths to suit your requirements. Thus the price of the Pergola illustrated, 25 ft. long, works out as follows:—

4 Arches at £1 each	£4 0 0
25 ft. run Top Bar at 1/6	£1 17 6
CARRIAGE PAID	£5 17 6

WHY IS IT SO POPULAR?

Read Free Booklet of Wonderful Results.

DIPLOMA AND MEDAL AT THE ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912.

Beware of imitations.
Genuine Only in Our Marked Bags,
Containing Guaranteed Analysis.

SCIENTIFICALLY AND CHEMICALLY PREPARED in the form of a leaf-mould, ready for use at any time, in the same way, and for all purposes that stable manure is put. Goes further (4 bushels equalizing 15 cwts.), gives better results, is clean to handle, sweet smelling, and free from weeds, worms, etc.

EVERY DRESSING OF WAKELEY'S HOP MANURE enriches the soil with the Humus it contains, doing lasting good, quite unlike the ordinary chemical manures, which act only as stimulants, and which, by constant use, impoverish it.

Cash Prices (including bags): Small (about 1 bushel), 3/-; Large (about 4 bushels), 7/-; 5 Large, 33/9; 10 Large, 65/-; 20 Large, 120/-.

Carriage paid to any station within 25 miles of London, including delivery within free delivery radius of Railway Company. 6d. per bag extra for every 50 miles or part beyond.

A beautiful Free Booklet giving full particulars and testimonials sent on receipt of postcard.

Sutton's Sweet Peas

By
APPOINTMENT.

A COMPLETE LIST of the finest and most distinct varieties will be found in SUTTON'S GARDEN SEED CATALOGUE for 1923.

We call special attention to our list of
SWEET PEA NOVELTIES for 1923
(On Page 160).

SUTTON'S COLOUR SCHEMES.

One of the most delightful methods of growing Sweet Peas is to arrange a number of varieties in harmonious blendings or contrasts. Excepting the two Frilled Mixtures, the Colour Schemes we offer are composed of our Giant Scented varieties:—

- 3941. Pink, Yellow and Salmon shades.
- 3943. White and Pale Blue shades.
- 3945. Pale Blue and Cream shades.
- 3947. Salmon-pink and Pale Blue shades.
- 3949. Rose-pink and Pale Blue shades.
- 3951. Cream and Maroon shades.
- 3953. Salmon-pink and Crimson shades.
- 3955. Imperial Red, White and Blue.

Each, per Packet, 2/6 and 1/6.

- 3957. Frilled White, Pink and Red shades.
- 3959. Frilled White, Mauve and Purple shades.

Each, per Packet, 2/6 and 1/6.

Awarded
17 GOLD MEDALS
during the
past three years.

SUTTON & SONS The King's Seedsmen **READING**

Notes from Maidstone.

SINGLE ROSES.

The interesting note of these charming flowers in January 6th issue reminded us that we can offer a good selection, and should specially recommend the following varieties:

*Irish Elegance,
Irish Glory,
Princess Mary,
Sheila Wilson,
Isobel,
Glow-worm and
Simplicity.*

These are all 1/6 each, except Cupid, 2/-, and Mermaid, 2/6

George Bunyard & Co., Ltd.,
The Royal Nurseries,
Maidstone.

CARTERS "VEG-VITA" GENERAL FERTILISER.

Carters

TESTED SEEDS

SEEDSMEN TO H.M. THE KING.

FERTILISERS — GARDEN AND LAWN

The whole of our compounded fertilisers are based on formulae which are the outcome of years of practical experience, each of which is now so accurately blended as to contain the correct proportion of organic and inorganic constituents necessary for the crop for which the particular manure is compounded.

CARTERS COMPLETE GRASS FERTILISER (No. 1)

is, as its name implies, a complete grass food; that is to say, it contains all that is necessary for the growth of fine grasses, but it does not force or burn them.

Sample Bag 1/3, 7lb. 2/-, 14lb. 3/9, 28lb. 7/-, 56lb. 13/-, 112lb. 25/-

CARTERS COMPLETE GARDEN FERTILISER (No. 6) (Veg-Vita).

The formulae are based on the average requirements of plant life, as a whole, and so accurately blended as to give splendid results to those who work for a mixed display, and do not specialise in any particular branch.

Sample Bag	7lb.	14lb.	28lb.	56lb.	112lb.
Price	1/3	2/6	4/9	9/-	16/6 30/-

CARTERS SWEET PEA FERTILISER (No. 7)

This highly concentrated fertiliser, if used in conjunction with deep cultivation, will grow Sweet Peas to show pitch.

Sample Bag	7lb.	14lb.	28lb.	56lb.	112lb.
Price	1/3	2/9	5/-	9/6	17/6 32/6

ALL CARTERS FERTILISERS ARE SENT CARRIAGE FREE.

For further particulars and price of Carters Chrysanthemum, Rose and other Fertilisers see Illustrated Catalogue "Garden and Lawn." post free.

CARTERS GRASS FERTILISER.

CARTERS SPECIAL POTATO FERTILISER (No. 12)

Ensures an increased crop with improved quality.

	7lb.	14lb.	28lb.	56lb.	112lb.
Price	1/9	3/6	6/6	12/-	22/6

CARTERS TOMATO FERTILISER (No. 8)

A well balanced fertiliser for producing healthy growth and well finished fruit of a good flavour.

Sample Bag	7lb.	14lb.	28lb.	56lb.	112lb.
Price	1/3	2/6	4/9	9/-	16/6 30/-

No. 2674.—VOL. LXXXVII.]

[FEBRUARY 17, 1923.]

THE USE AND ARRANGEMENT OF THE CROCUS

THE Crocus is just as suitable for naturalising as the Narcissus. It has, indeed, the great advantage of flowering at a season when flower is particularly welcome. Save some few harbingers of spring in rock garden and shrubbery and the always welcome but rather cold-looking Snowdrops, it provides our earliest flowers. Purple and yellow and white, there is more colour variety in the Crocus than in the Daffodil, and if there is less variation in form, there is variety enough. The immense selection of splendid Daffodil forms is rather a drawback than an advantage when we come to naturalise them, since we are tempted to use too many sorts and so to destroy the very desirable breadth of effect.

If we study natural groupings of bulbous plants or, indeed, of plants of any kind, we may find the species investigated growing in huge sheets or masses—Bluebells, Anemones or Campions in our own woodland, for example—or, at the other extreme, very sparsely; some plants of the easiest culture in gardens are never found growing profusely in nature. We may find a species with hillside or woodland practically to itself when in flower or in the closest association with another species or higgledy-piggledy with several other species. We may, accordingly, arrange our plants in a variety of different ways without outraging natural effect, but it is quite unusual to find more than two species of the race growing near together, and if we try to arrange two or three dozen different varieties of the same race (and flowering together) in one stretch of grassland, we are certain to destroy the natural effect which we had been at some pains to create.

The Crocus is an accommodating plant which grows equally well in garden soil or orchard turf, and can hardly be used ineffectively. It is largely used in serried

ranks to edge beds of spring flowers, and is very effective for the purpose, yet it is when seen in irregular, seemingly natural masses in not too rank herbage that it shews to best advantage. Thus it may be seen growing by the million at Warley Place. The great plantings at Kew are perhaps more familiar to many readers, though, in the nature of things, hardly so effective.

Fortunately, Crocuses and Daffodils may readily be grown upon the same ground, for, whereas the Daffodil prefers moderately deep planting, the Crocus likes a shallow root-run and, indeed, by its method of increase tends each year to get nearer to the surface, so that in ordinary garden soil the corms, if not lifted and replanted, ultimately appear above the ground. Under grass this is not, of course, feasible; the turf mat which allows passage of the tapered growth effectively holds down the lifting corms.

Those readers who have a stretch of grassland already planted with Narcissi may easily have a show of Crocuses next year as well, if they undertake the planting as soon as the corms are procurable in autumn. The turf may then be stripped fairly thinly, the soil beneath lightly pricked up and the Crocuses planted in irregular drifts. If

planting be left too late, the pushing Daffodil "grass" will, of course, be severed by the turf-plough. The yellow and purple Crocuses are most effective. They should be planted in separate drifts, but so used that the eye sees the two glorious colourings in combination. The white varieties, though less effective, may also be used either alone or among the purple ones.

Thinking and planning are really easier than planting. Do not spare the planning, therefore! See as much effective Crocus planting as possible now, while the sheets of blossom are in evidence, then study the lie of the land at home and arrange the groups to best advantage. Note the banks and let their swelling shoulders bear in February a garb of purple and gold! Let the hollows also receive their trickles of colour. If the edges of banks above old pits are harsh and unlovely in contour, it is not as a rule a very big task to round off the unsatisfactory corners and with the surplus subsoil—the top soil should be laid aside and returned—to soften the curves at the foot of the bank. Bold sweeps—not stiff escarpments—suit both Crocus and Daffodil, but, while eschewing pettifoggery variety, do not attempt to put an even lip all round a hollow. The appearance of artificiality must, at all costs, be avoided.

The Crocus is often planted on lawns. Such a course would not, however, commend itself to a turf expert! for either the Crocuses or the lawn must in the nature of things suffer ill-treatment. If mowing is suspended to allow the Crocus foliage to die off, the turf gets rough and progressively deteriorates. If mowing recommences before the Crocus "grass" is withered, the Crocuses are quickly exterminated. Nevertheless, the Crocus may be used in the mown sward of the wilder parts of the garden where Daffodils with their lingering foliage would be inadmissible.

CROCUSES AMONG GRASS AND FERNS AT WARLEY PLACE.

Some of the best of the Crocus is the one which is not all of us have started to grow. It is much to naturalise but it is not so easy to plant all our Crocuses in the one or a lot of it. There are few gardens nowaday in which there is not one corner where things are allowed for caused to look as natural as possible. The Crocus, thanks to its foliage, is almost as effective out of grass as in. Among Ferns or other plants which do not bulb in springtime it may be beautifully arranged, for the Crocus though effective when planted by the million, is equally so when grouped in a small garden in colonies of a hundred or so. Groups may be used to edify at this season the front reaches of the herbaceous border, which, if established, could now afford some background or pushing vegetation. Even in the paved garden, Crocuses are really more effective in irregular drifts than in the usual straight lines.

For naturalising in turf there is nothing to equal some of the many named varieties of Dutch Crocuses, but some of the Crocus species are very beautiful and worthy of more extensive planting. Readers will remember that two of these, *C. Tommasianus* and *speciosus*, received last year the award of garden merit from the Royal Horticultural Society. *C. Tommasianus* is an early-flowering and graceful species with pale sapphire-purple blossoms, and *C. speciosus*, blue and blue, is an autumn-flowering species and so somewhat out of the range of these notes.

The genus, however, extends to nearly seventy species, so that there is a great opportunity for those who like flowers in their gardens which are not to be found in those of their neighbours. *Crocus vernus* is, practically speaking, the purple Crocus of gardens. It is, even in nature, an exceedingly variable species with flowers ranging from deep purple to pure white. *Crocus Susianus* is listed usually as Cloth of Gold and as such is well known and deservedly favoured in gardens. Not only its glorious colouring but its earliness commends it to our attention, for Cloth of Gold always expands its blossoms before the purple and white varieties of *C. vernus* km. *C. biflorus* is sometimes called the Scotch Crocus, it comes from Southern Europe and Asia Minor or, more intelligently, as Cloth of Silver. The flower segments are white or, sometimes, pale lavender and the outer segments are distinctly feathered with purple. This species is seen to best advantage on slopes of the rock garden or in pans where the feathering can be appreciated, rather than in broad stretches where it does little but smudge the total effect. There are a number of geographical varieties, all beautiful and interesting. *C. Imperati* is an early-flowering species of robust habit and very suitable as a companion for *C. Susianus*, as it flowers at least a fortnight before the common *C. vernus*. In the typical form the ground colour is lilac purple, heavily feathered rich deep purple, but there are pure white and clear rose forms. *Crocus Sieberi* is a species from the Greek Archipelago, usually clear bright lilac with white at the base. There are, however, a variety of forms in many shades and combinations of colour from white to deep purple, all with the same feathery effect.

Crocus chrysanthus is another early spring-flowering species, it produces small orange-yellow flowers but there are pure white and sulphur yellow forms, the latter being very fine. The flowers are base colour of a pale yellow, and the yellow Dutch Crocuses, the white plants, are ranging the ground colour, striped with the red hue.

Other interesting spring-flowering Crocuses are *C. altavicus*, white, flecked purple, and *C. calypso*, a combination of deep purple and white, and *C. chrysanthus*, a deep purple and white.

A WEALTH OF BLOSSOM.

CROCUSES BY THE PATH SIDES.

CLOTHING THE SWELL OF A BANK

COLOUR IN THE WINTER GARDEN

THE cheerful way in which the early-flowering Heaths put up with the worst of weather at this season places them in the very front rank of winter-flowering plants. The white form of the alpine forest Heath (*Erica carnea* alba) is invariably the first to open with us, and one's only regret is that it is such a feeble affair. Perhaps, however, I should have added "comparatively," for in all fairness it must be admitted that it has a rival in the type species which is gorgeous enough to make anything less splendid appear rather more second-rate than it may actually be. But one can forgive the white *carnea* much for those few flowers with which it opens the New Year and ushers in that long succession which others of its genus will maintain for the following ten months at least.

Of *E. carnea* (syn. *E. herbacea*) one can only say that it is admirable in all its many forms. The type is itself first-rate, a hardy, easy doer in light loam or peat, and one that can be relied upon to flower profusely every year. It is a low-growing carpet Heath, making a compact growth about 9 ins. deep; the foliage is a soft, often yellowish, green; and the flowers which crowd the terminal shoots are, when fully expanded, a rich rosy red. Of the named varieties of *E. carnea*—a numerous family—some of them well deserve the praise bestowed upon them by nurserymen and patrons, while others appear to lack sufficient distinction. We all have our own tastes in such matters, but my choice in the *carnea* hybrids leans towards the deeper tints, one called *præcox rubra*, in a vivid carmine, being particularly striking and early.

E. carnea this year opened its first flowers here on January 10, a week or two earlier than *E. darleyensis* (*E. mediterranea* hybrida), which is another of the indispensables where winter Heaths are the object. This latter has all the precocity of *E. carnea* combined with the greater stature and more branching habit of *E. mediterranea*, it being a hybrid between these two. It does not, perhaps, always bloom quite so heavily as either of its parents; but it is a good thing, quite distinct, and its clear porcelain pink flowers are very charming.

Of *E. mediterranea* which, with the aforementioned, is said to prosper on a calcareous soil, one cannot speak too highly. It is seen in many forms which, when well grown, are all good. The type species may be described as a sturdy, upright, bushy-habited shrub of some 3 ft. to 5 ft. in height with dark green foliage and long terminal spikes closely packed at the leaf axils with flowers in a clear rosy red. In favourable districts the blooms begin to open at the end of February should the season be mild, and they will continue to increase until spring is well advanced.

E. mediterranea is hardier than *E. lusitanica*, which usually blooms a little later. Indeed, it appears to be able to withstand severe frost and biting winds without injury. Though the typical plant is so admirable for grouping, there is a form of it known as *E. m. superba* which is larger in all its parts, even more floriferous and more richly coloured. This makes an excellent specimen for the lawn or foreground of the shrubbery.

E. m. var. alba is, unlike the white *carnea*, a really fine white Heather, a prolific bearer of an abundance of long, densely flowered spikes of pure white. It is difficult to understand why such an excellent variety as this is comparatively so uncommon in gardens. There is a pretty dwarf variety (nana) of this species which is very suitable for the rock garden or edging and another (glaucæ) with a bluish-tinted foliage.

In its own way *E. stricta* is always very effective at this season, whether used as a low hedge or grouped. I refer not only to the very distinct foliage of this Corsican Heath, but to the dead flowers which glow with a warm, foxy red against the pleasing moss green of the stiff and fuzzy branchlets which bear them. The faded bells

resist all manner of inclement weather, keeping their fine healthy green untarnished and carrying their brilliant berries right on to spring. A group, mainly consisting of what are generally known as the Davis Hybrid *Pernettyas*, can always be relied upon to provide a crop of these fruits whose colours range from pure white through pink to rich blood crimson. Though very striking and large, birds seldom touch these berries, but I rather suspect that mice take their share sometimes. Apart from their beauty in winter, their red-stemmed spring growth and hoary little white flowers, the *Pernettyas* possess one further great advantage, and that is they never call for attention and with us never get any, and yet they are always fresh and neat.

MANY FORMS OF LING ARE BEAUTIFUL WINTER AND SUMMER.

of most of the summer-autumn blooming *Ericas* have their own peculiar winter colouring, soft tones of grey and russet brown, but none of them can equal *E. stricta* in this respect.

Then in the *E. vulgaris* (*Calluna*) set we have three varieties notable more for the colour of their foliage than their flowering, viz., *argentea*, *aurea* and *cuprea*. These might be described as good, better and best in the order given. The last named, i.e., *E. v. cuprea*, has, indeed, the most strikingly coloured winter foliage of all the *Ericas*, the lower parts turning a subdued gold which warms to a rich coppery hue at the tips. The form *argentea* is not as silvery as its name suggests, nor is *aurea* so golden, but, nevertheless, these are distinctly effective if happily placed in good groups. The best silver-leaved Heath known to me is a variety of *E. Tetralix* called, I believe, *E. T. mollis*, with white bells, and there is another fine variety of the same thing with very large blossoms in clear shell pink of which the leafage is distinctly glaucous in winter.

One must say a good word for the *Pernettyas* at this season for the splendid way in which they

Long before January is out the buds of *Forsythia suspensa* begin to swell and often in February the wand-like shoots will suddenly be wreathed with their yellow flowers. It may be contrary to orthodox practice, but I must say here that *F. suspensa* grown as a rambling bush overhanging a bank is a more pleasing object than the same thing severely pruned and thereby rendered stubby and void of grace. Moreover, it seems to me that a shrub like this, which is utterly destitute of leaves at flowering-time, and of which the blossom-colour is anything but striking, needs some background to be appreciated to the fullest possible extent. Here *F. suspensa*, always better when viewed from below, is grown on an Ivy-clad slope in the open woodland with pleasing results, as also is *F. viridissima*, though the latter is better off, inasmuch as it retains most of its leaves. With a similar background, including an old stump for it to trail over if it will, we have got the Winter Jasmine (*J. nudiflorum*), which, having some protection afforded by the branches of Oaks, is less liable to suffer from frost at flowering

time. Yet it must be admitted that the best we can do for this fragrant favourite is not so agreeable to it as the neglect which it enjoys in the little gardens of cottage neighbours.

It has been found that the screen just mentioned is often sufficient also to save the beautiful rosy pink flowers of *Rhododendron praecox* from destruction. These have been out some weeks, and they make a sweep of lovely colour on a westerly bank. *R. Nobleanum* gets a little of the same kind of protection, and the intense crimson of its wonderful trusses is in strong contrast to the chaste silvery pink of *R. Silberhad*, which this year has started unusually early. It sometimes might seem as if the rich and vivid colouring

of these and other *Rhododendrons* would strike a rather too exotic and incongruous a note in our winter gardens. Much depends, however, upon the way in which such plants are handled, and, after all, they are not alone, as I have tried to shew. The Heaths in themselves are sufficient in their colour display to dispose of any such suggestion and to invite further efforts towards harmonious companionship. NORTH WALES.

[It is a little surprising to see *E. carnea* and its white form written of as earlier flowering than *E. darleyensis*, which generally opens its first blossoms in November. Nor should we call the latter's blossoms porcelain pink. A very pale lilac rose would perhaps more accurately describe them.—Ed.]

WATER AND BOG GARDENING

II.—Planting.

IT is when the water garden is completed, filled with water and found to be watertight, that the question of planting comes up for consideration and it is here that the real joy of possession begins. Until then it has been a work of planning and carrying out, of earthquakes and planks and barrows, cement or bricks or puddling; necessary evils, but evils none the less.

With a clean sheet of water before one, with gently undulating margin, with stretches of bare earth and vision and imagination, what a world of possibilities lies before us! First of all I would suggest to go and stand by the water's edge and view it from various aspects, in order to pick out the most favourable places for massing a few trees, shrubs, or, may be, if the area is restricted, tall growing plants that will have a "reflection value."

The point selected makes a considerable difference and one should make quite sure where is the point at which this is greatest. Masses of flowering

Rhododendrons, giant perennials, placed where they will overhang the edge of the water, double their value when a brilliantly coloured reflection is flung back from the surface and so these should be our first consideration. It matters not what the area of the water may be, even the smallest rock pool demands this consideration and we should do well to give it our first attention.

Coming to the water surface itself, in the majority of cases by far the larger number of plants chosen will be Water Lilies and, with these, the best method of planting is to use shallow baskets. These should be filled with rich turf loam and half-rotted leaves, the roots of the plants firmly embedded in this, the basket tied together and then sunk in a suitable depth of water, varying, according to the vigour of the variety, from 1ft. to 2½ft. Another useful way, where a flat-bottomed concrete pond or brick tank is being planted, is to construct some openwork brick piers, cemented together when the pond is built, but leaving an ample openwork so that water can flow in, and roots and soil

make their way out. These pockets should be filled with soil as before and the roots planted in them, afterwards covering with water.

When planting or replanting is being done, no time is better fitted for this than late April and early May, for the temperature of the water is then well on the upward grade and the plants grow away rapidly and strongly. By the way, a note should be made not to allow *Nymphaeas* to remain for more than three years without division and replanting, for, after this time, the rhizomes become too crowded to do well and the result is that one gets too many leaves close together, so that they push one another above the surface of the water, thus spoiling the appearance of the flowers by partly burying them.

One's purchases should never be to the full capacity of the tank. One must have clear spaces of water between plant and plant, if one is to get the fullest effect and alas! water surface is small and the Water Lily very, very beautiful. But it will not do; the conglomerate mass is never pleasing, never satisfactory; there must be clear areas of unbroken water.

Other hardy aquatics, quite a number of which are native plants, by the way, may be planted much earlier in spring than the *Nymphaeas*, just before new growth is commencing being the best time of all, and similar practice is followed save that, in the case of some, tubs may be used, which are filled with suitable soil and sunk where required, while—in the shallowest water and for the dwarfest growers—small mounds or bays, constructed with bricks and filled with loam, are used. One should not confine oneself solely to what I may term "flat" plants, by which I mean those that rest upon the water surface only; add a few that rise upwards into the air, although rooting in the mud below the water. These are invaluable for diversifying height and, even in really small ponds, great value attaches to their restrained use, but one must avoid too many. They are, in many cases, bold, handsome and unusual, thereby adding a great deal of character, but one must avoid any appearance of competing with the flatter surface plants. In most cases they are best kept towards the edge of the water and colonised in small bays, perhaps intermingling one with another so as to give a more or less informal look, without studied grouping. To "dot" them in here and there among *Nymphaeas* is quite wrong and entirely spoils both. Keep your "flat" plants together and use your grasses and bushes to form strong "foregrounds," or, it may be, backgrounds; it depends upon the point of view and the position in which one may happen to be standing.

Another excellent service that these upright growing aquatics render us is as a wind screen to dwarfier plants which love to be quiet and unruffled, for, by planting the latter upon the south or west side of the taller growers, the latter form quite as efficient a shelter or screen as do a belt of shrubs or trees to a wind-swept garden.

Use all your knowledge of the plants in grouping and arranging, so as to get the very utmost possible out of them and see that the whole is linked together, as far as possible, there must not be a strongly defined line of demarcation between the water and the semi-aquatics or between these and the moisture lovers to which they lead. Each one should fall into its place, each one should lead to the other, so that a real and complete picture of exquisite softness and charm results.

In concluding these remarks upon planting, I would warn those with a good sheet of natural water against the depredations of the water rat. He is an evil beast, capable of working a considerable amount of harm before his presence is detected or suspected, and a war of extermination should be waged against him. H. W. CANNING-WRIGHT.

THE BOG BEAN, *MENYANTHES TRIFOLIATA*.

WINTER FLOWERS AT READING

A RECENT pilgrimage to Reading to see what Messrs. Sutton are doing this season with winter flowers was exceedingly profitable, since both *Primulas* and *Cyclamens*, if a little past their best, were in excellent form, while some batches of *Cinerarias* were sufficiently advanced to shew

new crimson which will one day—when it can be persuaded to seed more freely—be a gorgeous novelty. Even the coral pink varieties pale their (comparatively) ineffectual fires before the glorious Symmetry which Messrs. Sutton class with the stellata forms, but which is in reality an improvement upon both Star and Show types. Of a

IMPROVED GIANT WHITE STAR MIGHT BE DESCRIBED AS AN ALBINO SYMMETRY.

their character. Most readers of *THE GARDEN* will know that Messrs. Sutton's trial grounds are the place to see a wonderful collection of Chinese *Primulas*. As usual, the results of cross pollination as evidenced in the first, second and third generations were of extraordinary interest, though in the vast majority of cases no striking advance is manifested in the produce of these crosses. One singular result may perhaps be worth mention. The fiery crimson *Etna* was crossed with *Giant White*. In the first generation (F_1) two forms were produced, one an old type of white-flowered *Primula* and the other a salmony-pink form, also of out-dated type. This production of two forms in F_1 of course, irregular; but, more singular still, instead of breaking up in the usual way in F_2 , these F_1 forms reproduced themselves true and have since proved to be fixed. This is obviously a case of reversion to type, but it will not be easy to fit into the Mendelian Laws as at present understood.

There is no need to run through the list of lovely varieties of *Primulas* in flower. There are some to suit all tastes and most of them are familiar to all lovers of greenhouse flowers. There is not one variety of all those offered in Messrs. Sutton's list which has not real claim to inclusion, which is not, in fact, well worth growing, though, naturally, individual tastes and preferences are catered for. All visitors to Reading this season will, however, agree that the main interest does not centre in the glorious dark *Etna* nor even in that splendid

glowing cerise rose shade, with substantial five petalled flowers, well rounded but not overlapping, carried on stout stems well above the beautiful foliage, this is certainly the *Primula* which an amateur should grow if only one variety is wanted. *Giant White Star* is a pure white counterpart to this, big and bold and handsome, yet had the writer to choose two sorts for his own purpose (and were strictly limited to two) he would select *Silver Star* as the companion. This is a perfectly eyeless white variety with purple foliage. The flowers are not large, but the plant is imbued with grace and breeding and the unbroken silvery sheen of the blossoms when grown in mass must be seen to be believed. This, by the way, is a splendid variety for cut flower. *Enchantress* holds roughly the same position with regard to *Silver Star* that *Symmetry* holds to *Giant White Star*, which is to say, it is a rosy-crimson variety without the characteristic yellow eye. Except for a touch of white at the narrow throat it is self-coloured. This is also a valuable sort, though compared with *Silver Star* it looks ordinary enough.

Before leaving the sinensis *Primulas* it may be well to mention that Messrs. Sutton have what is (or was) supposed to be the type plant as collected in China by Wilson. Messrs. Sutton have only a few plants of this really beautiful species. To appreciate it, one should look out for it in No. 4 house at Kew. It is not thought at Reading that this plant can be the progenitor of the greenhouse *Primulas*, for, despite repeated trials, it refuses to

cross with the florists' forms. To point to its lack of similarity alike in flower and foliage would perhaps be presumptuous, but it may be permissible to mention that the foliage of the species has a very pleasing *Primula* scent, quite unlike the rather rank smell of the cultivated varieties.

Messrs. Sutton are not flowering their obconica *Primulas* until later in the season, but one could hardly fail to notice a batch of *P. malacoides* in its best forms—it still re-selecting—as little like the original plant which some of us have already half-forgotten as—well! a great-dane is like a small fox-terrier. It will be surprising if, when this strain comes on the market, it does not cause something of a sensation.

Among the *Cyclamens* one, naturally, looked out for *Firefly*, which recently received the R.H.S. award of merit. Though not a large-flowered variety, this is certainly a brilliant one and in a better light the faint blue tone noticeable on a very dark day at Vincent Square, could not be detected. Messrs. Sutton have at least three other brilliant red strains which they are working up and will one day be able to offer. To catalogue all the splendid varieties on view would be tiresome. Suffice it to say that the *Silver-leaved Salmon*, with foliage as handsome as a *Rex Begonia*, was, as usual, in evidence, also the beautiful fringed forms and the large-flowered sweet-scented sorts. Messrs. Sutton point to a wonderful improvement in size with these last. To us it seems that they might claim at least an equal improvement in form! The so-called double-flowered *Cyclamens* make no appeal to the writer, but it must be admitted that they are wonderfully fragrant.

The *Cinerarias* will, a little later on, make a gorgeous display. Even now there is sufficient flower to assist a would-be purchaser in making a selection. *Cinerarias* do not breed true to colour, in the way that *Primulas* can be selected to do, for instance, but Messrs. Sutton have succeeded in so selecting their large-flowered forms that they come true to general colour. The white selection is pure white and constant also to type, the blue comprising several tones of deep velvety blue and purple, the light blues are mostly beautiful china-blue shades and the pink shades are all lovely, some of the china pinks being marvellously beautiful. Sutton's *Scarlet* represents the vivid colouring of the German *Matador* strain, which was very weedy in habit, on plants of the best form and with large and handsome flowers. The *Star Cinerarias* are still popular, but undoubtedly as they become better known the "Intermediates" will largely supersede them, especially the charming *Forget-me-not Blue* which comes wonderfully true to form and colour. The flowers are considerably smaller than those of the large-flowered type, but shapely and produced in extraordinary numbers. With the *Cactus-flowered Star* varieties most readers will by now be familiar, but the splendid *Feltham Beauty* strain is hardly so well known. The plants of the strain are more compact than the true "Stars" and the flowers, though of *Star* shape are larger. The hall-mark of the *Feltham Beauty* strain, however, is the white eye to the blossoms, which gives the whole inflorescence a very light and graceful appearance.

FORTHCOMING EVENTS.

THE ALPINE POPPIES

WHEN I was a boy I once came on a "pierrier" not a moraine—in the chalk Alps of Savoy (Jalouvre) where I really thought I had found the terrestrial Paradise. *Thlaspi rotundifolia*, *Saxifraga cava*, *Valeriana triptens* and *Ranunculus parnassifolius* were there in quantities, but they all "took a back seat" before the altogether delightful white form of *Papaver alpinum* (*P. Burseri*). Hundreds of silk-like and crystal-pure white corollas shivered under the glacial wind of the high Alp, and their delicious fragrance transported me. Myriads of bees were busy collecting the pollen in the rich sheaf of stamens forming the heart of the large white flower. The plants formed big patches bearing, some of them, nearly fifty flowers, and were wonderfully beautiful. I decided, then, to devote myself heart and soul to that plant only; but it was only a child's ideal, and since that time I have seen so many treasures in the high Alps that I was obliged to enlarge my heart.

Never mind! The Alpine Poppy remains one of my "flames"! It is, in the Swiss Alps, not at all a common plant. You may find it here and there. In our neighbourhood the white form is indigenous, and it is glabrous and glaucous, and grows in damp or rather moist, cool places (*coulours* and *éboulis calcaires*). Its finely cut leaves are all slit and slit again into thin strips until the effect is very fine and fern or fennel-like, and the leaves are almost hairless and of a grey tone. Seen in its natural site the plant is a real beauty; it is impossible to describe its grace and its charm. I think it might be compared to a minute and Lilliputian *Romneya trichocalyx*; its scent, too, is delightful, but its charms are as fugitive as its beauty is exquisite. Take a bunch of the flowers and when you arrive home there is nothing left. It is best to cut them in the bud state; then they open well, but do not, alas! last long in water. The white form of *Papaver alpinum*, called *Burseri* by Crautz, is rare. You may find it in the Vergy ranges (Haute-Savoie), on the Dent d'Oche (idem), in the Prealps of Fribourg and of the Bernese Oberland.

Then, again, you may find it on the north side of the Tyrol. It is quite a distinct plant, and when once found will never be forgotten. Quite different is the hairy plant called *P. pyrenaicum*, or *aurantiacum*, which grows in very sunny places, generally in *éboulis* or in moraines, and sometimes even in rock crevices. The plant is more or less hairy, the hairs being rather yellow or brown and sometimes very thick. The flowers are yellow or orange or even red. I have found it in the Pyrenees, on the Maritime Alps and on the Mont Ventoux, where it forms big patches, growing even on the wide motor road!

Of course, all these Poppies are south-western and alpine forms of the Iceland Poppy and originally they came from the north (see the most interesting book of Dr. H. Christ, "*La Flore de la Suisse et ses origines*"). They are very variable. I have grown them all in our alpine botanic garden at the Linnæa (see H. Correvon, "*Cat. des plantes du Jardin bot. alpin de La Linnæa, Geneva*," 1901, page 19), and made, from 1889 to 1900, interesting experiments with them. But after I introduced some plants of *P. croceum*, brought from Central Asia by my friend, the traveller Bonvallot, it was impossible to keep them true. The bees work hard upon them and they cross with extraordinary facility, even when the various species are planted far apart. We planted the Asiatic plant on the other side of the hill bearing the garden at Bourg St. Pierre

(4,900ft. alt.), and I thought that this would be sufficient to hinder cross-pollination. The bees, however, did their work as well as if the plants had been close together. The results were that we had a considerable number of distinct shades, tints and forms and that we could do no more scientific work.

The types are: *P. Burseri*, which I described first of all; *P. aurantiacum* or *pyrenaicum*; then *P. Rhaticum*, near to the last, bearing, however, much larger leaves; *Kernerii*, with small, very short, smooth leaves divided into obovate divisions, sometimes red and short-stalked. It originated in the Dolomites and in the Julian Alps.

I have planted it or sown it in many alpine stations and gardens in the Alps. It always grows there like a weed and encroaches a good deal, but it is at its best in gravelly, sandy soil. We have on the Jura a piece of ground as a subsidiary of *Floraire* for the raising of the seeds;

there, in a very sunny and dry place, we sowed a mixed packet of our alpine forms, the Pyrenean one excluded. We had such a beautiful result that many people went from Geneva up to St. Cergues to admire it.

The flowers became much bigger, and they gave a kaleidoscopic effect with their different shadings and tones of colour. Some are pure white, others deep or light pink, red or crimson or sulphur or pure yellow. Some blossoms carry two colours, while some even came with double flowers. We had, too, a lot with very large flowers we called *grandiflorum*.

For their culture in lowland gardens it must be observed that it is a necessity to give poor, rather stony and gritty soil with exposure to full sun. What gardeners call "moraine" should suit them well, but the wall garden is best of all for damp climates.

Floraire, Geneva.

HENRY CORREVON.

WHY?

EVERY garden-lover who visits many gardens develops a mental note of interrogation. Why was a certain line taken here, a particular planting introduced there? The self-asked question is not always satisfactorily self answered. Sometimes the reason is obvious after a moment's consideration; at others, even though the result is quite successful, the intention of the designer or planter remains obscure. I have often wished that I could get at the person who first conceived

a certain garden arrangement and find out exactly what influence was at work to decide a course of action of which I am seeing the effect. Sometimes when able to do so the result has been disappointing, for the reason that the effect obtained was an accidental one produced by entirely haphazard methods. More haphazard work is done in the garden than anywhere else on earth. True as this is about design, it is more emphatically so with regard to planting. The mere possession of a few shrubs or plants, a possession that may

be quite accidental, is sufficient reason for finding a place for them in the garden. What is worse still, one often finds distressed remnants of ornaments that have long since lost any claim to beauty they ever held, and are now merely old, dotted about, disfiguring an otherwise attractive garden. The only reason for them being used at all was that they happened to turn up and places were found for them. Apply this principle to any other department of domestic life and its absurdity becomes patent. Would the discovery of a keg of paint in an outhouse lead anyone to start redecorating his home? Certainly not; and if the paint was of a different colour to that already used, even though certain portions might need repainting, it would be considered little short of madness to use it. Nor would anyone finding a few old gully trap gratings or drain pipes promptly start introducing a new drainage system into his grounds. But let the same person discover in a barn that is being cleared out the headless trunk of an old stone figure, and it is promptly invested with romantic associations, a council of the family is held which debates seriously on the spot in which it shall be placed, and usually decides on one where it will most prominently disfigure the garden scene. Sometimes by chance the "find" is respectably good and the spot chosen suitable, when the result is happy; more often it is the reverse.

Two questions of this sort arose to my mind when visiting the

A FIGURE PLACED WITH A PURPOSE.

gardens at Burrswood, Greenbridge, last summer. The first was with regard to the figure placed in a somewhat unusual place on the terrace. An exquisite piece of modelling in itself, I could not help admiring it, but wondered why it was placed in just that position. When I reached a point at some distance from the house and looked back I knew. Placed in the angle of the house it was easily the strongest and most appealing note within the view. One looked first at the figure, marvelling at the beauty of the pose and the suggestion of lofty aspiration it conveyed, and then as the eye followed its upward stretch it was caught by the luxuriant masses of a towering *Wistaria* that covered one side of the angle. Man's art became an incident that only served to reveal the beauty of Nature in one of her most beautiful aspects. Looking down once more the figure appeared to sink into insignificance, though losing none of its beauty; but one could not help being struck by the charm of the combination.

The second Why? (in the same garden) was the wonderful mass of *Choisya ternata* planted here and thus. On putting the question to the present owners of the garden I found they were as much at a loss to understand it as I was, although we all agreed that being what and where it was it could be left. Backed by a hedge of noble proportions, evergreen, it fills the border for a considerable distance. In itself it is a simple and beautiful thing, but there is a sense of incongruity in its position in the garden that is not easily overcome, and one is compelled to wonder if its introduction was the result of accident or design. Was the gardener who planted it so fond of its glossy green foliage and fragrant white flowers that he indulged in a *Choisya* debauch and planted this long straight line of it with the resolve that whatever else might happen in the garden here at least he would find something to rejoice in. Or was it that he had a very successful striking of cuttings and just planted them in the border to get rid of them? Whatever the reason, it cannot be denied that the result is successful from the point of view of cultivation, and this fragrant snowy bank is delightful enough, although a trifle monotonous. As an example of how well this "Mexican Orange" will grow and flower in favourable conditions it is remarkable. The plant is, of course, hardy in the South of England and succeeds in many places in the North.

Yet a third Why? arose to my mind a few days later in another garden. Why was *Wistaria multijuga* placed in such a position? Anyone knowing the habit of this beautiful climber would realise that the wall behind is not of sufficient height to keep it as a climber, for which it is most suitable. The individual racemes starting from the top of the wall would sweep the ground. For this reason it was allowed to grow as a bush. This is another instance where the exceeding beauty of the plant has redeemed it from the failure that the choice of position warranted. Grown as a climber, as in the fourth illustration, where its lilac lavender flowers can fall naturally from among its delightful ash green foliage, it is one of the most wonderful of all climbers, and certainly the best of all the *Wistarias*.

It may seem a little thing, this choice of position for every detail that is admitted to the garden; really it is the greatest factor of success or failure. The best and most successful garden is the one in which the composition of its details is as carefully considered as is the arrangement by an artist of all that goes to make a good picture. In fact, the good gardener is an artist, and the good artist, if it were possible for him or her to acquire the necessary technical and cultural knowledge, would make the finest gardener in the world.

GEORGE DILLSTONE.

A HEDGE OF *CHOISYA TERNATA*.

WISTARIA MULTIJUGA—BEAUTIFUL BUT WRONGLY PLACED.

THE SAME SPECIES ON A HIGHER WALL.

A STORY OF A SEARCH

I must be a dozen or more years since I first began to want and to look for the Mt. Cenis Rest Harrow, *Ononis cenisia*, and it was not until 1922 that I first possessed and flowered it at Stevenage. Farrer and I hunted high and low for the plant when we were at Mt. Cenis together, and failed utterly to find it, and I have hunted for it there twice since with the same result. As a matter of fact, I believe that just as there is no such mountain as Mt. Cenis—only a pass named after a mythical mountain—so *Ononis cenisia* does not grow at the place after which it is named, but only on the road leading to it.

Mr. Stuart Thompson in his "Alpine Plants of Europe" gives "the plateau behind the Hospice at Mt. Cenis" as a station for the plant, but I do not think that careful observer ever found it there himself. Probably he was quoting some authority with a gift for "exaggerating things which never happened." For I put the whole of that plateau through the small sieve, quartered and fine-combed it for hours, and finally convinced myself that not only does *Ononis cenisia* not grow there, but that it never reaches such altitudes. You only begin to find it when you get down below Landelebourg. I saw it there by the roadside as I trundled down in a motor *chars-à-banc* in July, 1920. And it was from a *chars-à-banc*, too, that I first found the plant a fortnight earlier. We were going up from Grenoble to La Grave. A mile or so below that village I saw on roadside screes a brilliant little pink and white Rest Harrow, perfectly prostrate, and felt quite sure it must be my long-sought *Ononis cenisia*. I was so thrilled that directly after dinner that evening I hurried back down the Grenoble road and groped about in the dark on the screes, striking matches until I found my *Ononis* and satisfied myself that it was *cenisia*. It is rather *banal* after longing and looking for a rare alpine for a dozen years to spot it finally from the back seat of a *chars-à-banc*, growing in thousands by the roadside. However, motor coaching in the valley of the Romanche is not without thrills. The road runs like a mantelpiece on the sheer cliff, and you get glimpses of the river down on the hearth 500ft. or 600ft. below. At every hairpin corner of the mantelpiece our driver developed a tickle in his left ear which he elaborately scratched with his right hand. These tricks of his, however, were wasted on us. We were already too scared to be further scared by them. Next morning I returned to my *Ononis* screes and dug up a goodly number of youngish plants, and very nicely they came up from the loose, stony soil with good mops of fibrous root. When I got them home they settled down and grew for a week or two—and then died, every one of them. Why, I could not imagine, but they did. After La Grave and a few splendid days at the Lautaret I met *Ononis cenisia* again, and with it more dreadful adventures. We wished to get from Lautaret to Briançon, and we wished to drive. A M. Simon and an ancient phaeton were produced. There were three other passengers, two French airmen and a small French girl. We packed into a seat at the back. A few miles down the Briançon road *Ononis cenisia* became plentiful, little solid clumps of warm rose and snow white all along the roadside, and here and there *Campanula Allionii* in great colonies of almost stemless Canterbury Bells among the loose stones. And just when these two rarities became most plentiful and brilliant, things began to happen. The two airmen in front grew uneasy

and peered over at the ramshackle wheels, the wheels wobbled and rattled as our pace increased, M. Simon kept saying "Oh! oh!" the airmen said they would rather be in an aeroplane, and then very tactfully our horse, which was running away, brought us up with a jolt in the ditch and stood kicking the phaeton to pieces, which was the best thing he could do with it. He was so successful that another conveyance had to be fetched from the nearest village. After a long delay, during which we studied *Ononis cenisia*, we all repacked ourselves in the new conveyance, and, when the passengers were in, there was no seat for M. Simon. However, he fixed himself on the little iron handle of the brake—one of those that you wind round and round—and thus secure he went sound asleep. We had a good sensible horse, however, for with one rein lying in a serpentine along his back and the other hanging in a loop within rin. or zins. of the ground, he safely conveyed us and the sleeping Simon the last eight or ten miles to Briançon. But this, which was to have been a note on *Ononis cenisia*, seems to have degenerated into a tale of high adventure in the Alps. At Briançon, within an hour's walk of the town, we found *Ononis cenisia* again, and in great profusion. No wonder

I had never found it at Mt. Cenis. It is not a high alpine at all, but a sub-alpine, and oh! such a lovely little thing. The largest plants are 1ft. across, and their wiry stems lie flat upon the ground, radiating in all directions from a common centre, and all set with perky little stemless pea flowers with standards of warm, bright rose pink and keels of pure white. The only other plant which interested us at Briançon was Mistletoe growing on Scots Pines, *Pinus sylvestris*. I had never seen Mistletoe on this host before.

In July, 1921, I returned to the Lautaret and walked far down the Briançon road to collect *Campanula Allionii* and seeds of *Ononis cenisia*. But it was a bad year for seeds, and after examining hundreds of plants I only secured a couple of dozen or so seeds. These germinated well, and this last summer (1922) I flowered *Ononis cenisia* at Stevenage for the first time. My two or three planted-out plants on the rock garden look extremely well (all the others of the crop were long ago dispersed) and none the worse for such frosts and rains as the present winter has already given them. For *Ononis cenisia* I would recommend light gritty soil or moraine and the fullest, hottest sun to be found in the rock garden.

Stevenage.

CLARENCE ELLIOTT.

SOME WOOD SORRELS

THERE are few choicer looking British native plants than the Wood-Sorrel, *Oxalis Acetosella*. Showy it is not, though at dusk its fragile veined-white blossoms shew up in a way they never do by day. It is certainly worth naturalising on shady banks in the garden for, though quite easy in shady corners, it never encroaches into the sunlight. There is in commerce a pretty pink form also worth growing.

Not all the Wood Sorrel family, however, are so retiring either in colour or in nature. The brilliant and floriferous *O. rosea*, for instance, usually considered a greenhouse plant, makes a gorgeous display on a ledge with a warm exposure and, if an unusually hard winter kills off the plants, self-sown seedlings are almost certain to appear in near-by crevices the following spring.

O. corniculata, with splendid bronzy foliage, is likewise killed by hard frost, only to renew itself from self-sown seeds.

In fairly gritty soil with a westerly exposure, *O. enneaphylla* will succeed and most rock gardens now contain it, but *O. adenophylla*, of which a picture appears below, likes rather a sunnier aspect. The two plants have many obvious similarities yet, seen side by side, they are quite distinct. Perhaps *O. enneaphylla* has rather the choicer look, but *adenophylla* is certainly freer to flower. Both are typically white, mauve tinted, and both have so called "rose" varieties which are, only slightly deeper in colour than the type.

Less commonly seen is the golden blossomed *O. lobata*, a Chilean species, which flowers in late autumn and is accordingly valuable. It likes a sunny corner.

AMONG THE CHOICEST OF ROCK PLANTS, *OXALIS ADENOPHYLLA*

THE BEST OF THE RAMPIONS

PHYTEUMA COMOSUM, if not a rarity, is one of those plants you find only in special gardens, where it is tended as a treasure of high value. I saw it here and there in English rock gardens and sometimes on the Continent, but it is nowhere common

looking rather like cast-iron, and their teeth are narrow and sharp and look as if they would bite those rash individuals who attempt to molest it.

"Sitting, as it seems," says Farrer, "among the scalloped leaves of sombre greenish-black, unfold the clusters of immense diaphanous, yet solid flowers like bunched soda-water bottles of pale purple, deepening to their tip, from which the curly stigma goes frisking forth in manner weird and wild. It is indeed the strangest of all children of the cliffs, and, I may also say, the hardest to

dislodge." That description is the best I have ever read of this curious denizen of the cliffs, which seems rather a beast than a plant when seen in the dark and shady walls.

We succeed with it here only in a north wall, but in English gardens I have seen it very happy and in some cases (by Mrs. St. Quintin at Scampston Hall and Dr. Jenkin at Hindhead, for instance), better than I ever saw it in nature. They grow it in well drained pots and, as can be seen by the illustration, bring it to perfection.

Geneva.

H. C.

PHYTEUMA COMOSUM GROWING AT HINDHEAD, SURREY.

in cultivation. In nature, however, it is a common thing, at least in its special habitats. You may find it not far from Milan in the north side of the Monte Barro (Brianza), and on the Corni di Canzo, as well as on all the mountains of Lombardy, Bergamo, South Tyrol, in the Dolomites, all over the Lago di Garda, in the rich and picturesque Val di Ledro and up to Dalmacy. Near to Bellagio, at the foot of the rich Grigna, from Lecco to Bellano, and from Bellagio westwards you may take it from the boat if you follow the shore of the lake. There the *Phyteuma* hangs from the rocks and the garden walls just above the lake. In some cases even, the waves break upon it. In the vicinity of Storo (Judicary), and at the foot of the Monte Tombea, it forms enormous tufts of great beauty. In some parts of the Dolomites it is in such quantities that the walls are covered with it.

But how hard to collect it! It sends its fat and fragile roots into the narrowest crevices of hard rocks, especially dolomitic ones, and there one may try and try again. One has the greatest trouble to extract the plant. The best thing to do is to try to find it in some locality where the stone is of friable nature, such as slate, for instance, which is easily broken down. I once found in the wild Vestino Valleys (Lago di Garda), a corner where it grew in old rotten slate cliffs, whence the plant was very easy to extract. Generally speaking, the best means of collecting the plant is to seek it at the foot of the walls, in the heaps of debris (pierriers), where one sometimes finds young ones which are condemned to die, as the plant can never reach maturity elsewhere than in the crevices of rocks. Such is usually the case with all saxatile plants (*Primula Allionii*, *Potentilla Saxifraga*, *Saxifraga florulenta*, etc.).

In the cliffs with a north aspect which it haunts, *Phyteuma comosum* displays its tufts of dark metallic green foliage, which are in themselves a curiosity. The leaves are thick and leathery,

will range over Hollies and Rhododendrons to a height of 15 ft., and more, wreathing them with ropes of scarlet from midsummer to autumn and giving in addition an attractive display of china-blue fruits which produce an abundant crop of seedlings.

It is probable, however, that most gardeners, no matter where they are situated, could grow this handsome climber if the right conditions were accorded it. In the first place an aspect should be selected that is not exposed to the full noonday sun. *T. speciosum* really delights in sun, or rather its upper, or flowering parts do, but its stems and roots should be in shade. The most suitable medium is any free loam liberally intermixed with leaf-mould, well decayed vegetable rubbish and some really old cow manure, this being worked to a depth of 2 ft. at least. The roots should be planted 3 ins. deep in this, just when growth is commencing in spring, and an ample supply of moisture during the first summer is essential.

Those who have tried other means and failed may coax *T. speciosum* into prosperity by this means:—Make a hole, or trench, 3 ins. deep, thoroughly loosening the soil at the bottom, and

THE FLAME NASTURTIUM

THOUGH *Tropæolum speciosum* is not everybody's plant, there are few who have not tried to grow it. A weed in some districts and a plant that refuses to endure life in other places, no matter how great the care lavished upon it, the Flame Nasturtium, naturally, inspires no little interest, apart from its undeniable attractions. It is not that it is tender. Far from it. The warm and sultry south is what it dislikes, a cool aspect and root-run in the north or north-west being its chief delight. In some gardens it

half fill this with the above compost. Now set the roots in the sunk bed, the surface of which will be some 18 ins. below the ground level. Then, when the shoots are about 6 ins. high, commence top-dressing with more of the compost and continue to do this as growth proceeds until the bed is about a hand's breadth from the top, and it is unlikely that one's labour will go unrewarded.

Some have had better results with seed, but in my experience this should be sown in autumn, and the sunk bed may be adopted where there is reason to suppose there will be any difficulty. In any case the Flame Nasturtium has so many excellent qualities that it is worth a deal of trouble.

By way of indicating the variety of uses, other than as a wall covering, to which *T. speciosum* may be put, I may add that our best plantation is in a bed of deciduous Azaleas, whose branches, after the flowers are over, are festooned with masses of brilliant colour. A neighbour grows this plant most effectively among various dwarf shrubs on the northerly slope of a bold piece of rock gardening and yet another, as I have suggested, has established it among the evergreens and flowering trees of open woodland.

CAMBRIA.

SCARLET BLOSSOMS OF TROPÆOLUM SPECIOSUM.

CORRESPONDENCE

PLANTS FOR SWITZERLAND.

I WAS interested in M. Correvo's little note on sending plants to Switzerland. (page 35) as I am temporarily held up from sending plants to France, Italy, Holland and Switzerland including some for M. Correvo himself, though not having performed certain antics which the postal authorities of Stevenage tell me are necessary before I can send plants to these countries. Our Post Office refuses to receive parcels of plants for France, Switzerland, Italy and Holland unless they are accompanied by a Phylloxera certificate, and to obtain this it seems I have to have an expert down from the Board of Agriculture, paying a fee of 2 guineas, as well as the expenses of the gentleman's little jaunt into the country. Not long ago it was enough, in sending plants to France, to capture a Justice of the Peace and get him to perform certain mystic rites and incantations with a Bible. This seemed quite to satisfy the Post Office folk, but now they insist on the more expensive measures. It would be a great kindness if the Editor of THE GARDEN would investigate the whole matter and publish authoritative information for the use of readers of this paper.

If M. Correvo and the Swiss Government are right, then it would seem that our own Ministry of Agriculture and Postal Authorities are wrong and have been misleading myself and other English folk who are wanting to send plants abroad.

M. Correvo suggests that English nurserymen should "deal firmly" with the Post Office. But for an individual to deal firmly with a Government department is about as easy as for an individual to deal firmly with, let us say, a quacksand. If the Swiss Authorities do not require or desire any Phylloxera certificate, why should our own Postal and Agricultural Authorities insist on our going to the expense of procuring it? The older joke of getting a Justice of the Peace, who had never heard of Phylloxera, to swear on the Bible that none existed within so many rods, poles or perches of one's alpine was vexatious, but comparatively harmless and not expensive. This later development, however, threatens to be a serious menace to trade.—CLARENCE ELLIOTT, *Stevenage*.

THE EARLY SEASON.

THOUGH the winter has doubtless been extraordinarily mild all over the country, growth here has never within memory been so forward as it is at the time of writing (January 20). In addition to the usual winter-flowering bulbs (Snowdrops, Eranthis, etc.), which, by the way, were not abnormally early, the following are already bearing fully expanded blossoms: *Prunus Pissardi*, *Rhododendron præcox* and *R.R. Silberhad* and *Nobleaunum*, *Berberis Bealei*, *Daphne Blagayana*, *Azara microphylla*, *Omphalodes cappadocica* and *O. nitida*, *Anchusa myositidiflora*, *Erica carnea* and *darleyensis*, *Cistus rosmarinifolius*, *Gentiana acaulis*, *Genista fragrans* (quite unprotected), *Primula denticulata* and various blue Primroses, *Saxifraga Boydii alba*, *bursiculata*, *apiculata* and others, *Cheiranthus Allionii*, *Pulmonaria Mrs. Moon* (always the first of its tribe here), *Vinca minor* in several colours, *Polygala Chamæbuxus purpurea* (exceptionally good) and a number of other little things. There are shoots on hybrid Clematises 6 ins. in length, and such shrubs as *Exochorda grandiflora* and several *Spiræas* are in almost full leaf. It is also worthy of note that woodland Daffodils are in bud, and many last year's Californian annuals are not only still surviving, but bright with flowers on any sunny day.—A. T. JOHNSON, *Iltycafu, North Wales*.

A LITTLE-KNOWN SHRUB.

THAT interesting plant *Philesia buxifolia* belongs to the Natural Order of *Lilacæ*, and is closely allied to the better-known greenhouse climber *Lapageria rosea*. It is quite hardy in many parts

THE ROSY-RED PHILESIA BUXIFOLIA.

of this country, being especially happy in the moist, hilly districts of the west coast. The plant illustrated is growing in an Essex garden, where it is quite at home, growing and flowering freely. *Philesia buxifolia* was first discovered by Commerson in the Straits of Magellan, but it also extends along the west coast of South America as far as Chili and Valdivia. In the latter country it is known as *Pepino*, and is found at the summit of the Cordillera growing in marshy places under *Alerce* trees. It was first introduced by Messrs. Veitch of Exeter through their collector, Mr. Lobb, and exhibited in flower at the Chiswick Flower Show in June, 1853. In its native country it forms an erect, much-branched shrubby plant 3 ft. to 4 ft. high clothed with narrow evergreen leaves 1 in. to 1½ ins. long. On the tips of the branches the large solitary drooping flowers are produced in June. They are somewhat waxy in texture and rose red in colour, and from 2 ins. to 2½ ins. long. A hybrid has been raised between *Lapageria rosea* and *Philesia buxifolia*, and is known as *Philageria Veitchii*. It is a half-hardy scrambling shrub—W. I.

THALICTRUM ADIANTIFOLIUM AND ITS HARDINESS.

AS the above is a native species, it is difficult to account for Mr. Linders Lea's experience as to its tenderness. *T. minus* (the specific name)

varies considerably in size and other features according to soil and locality, and *T. m. adiantifolium* is one of these forms. It is possible that some of the best garden varieties (*i.e.*, the most glaucous) may prove somewhat tender inland when their place of origin is the sea-coast. A plant from stock secured from the Great Orme's Head, for example, might feel the pinch of winter rather severely on a Staffordshire moor; but I have always understood *T. minus* to be distributed fairly abundantly throughout the limestone of Northern Britain. Our own stock, quite a pretty form, was gathered near Buxton, which should be bleak enough to test anything.—N. WALES

WITH reference to the hardness of *Thalictrum adiantifolium*, I may say that I have grown it for some years and have found it to be quite hardy in the heavy soil of my garden. I have never given it the least protection during winter, yet it has not merely survived, but it has increased considerably.

With the intention of bringing it indoors occasionally I planted a clump in a pot, but there was such a marked contrast between it and that in the ground that it was quite useless for the purpose I had in view. It never looked healthy and died down for the winter a month or more earlier than the others.—G. W. WEBB, *West Wimbledon*.

MANY years experience of the Meadow Rue,

referred to by your correspondent in the January 27 issue of THE GARDEN, is that it grows like a weed. I have it running riot among a lot of tall Irises and a ruthless extirpation is needed to keep it within bounds.

May I add a word in praise of the *Stranvaesia undulata*. Its spreading habit—one of mine is 4 ft. high and 14 ft. across—in no way detracts from its charm and the birds which in former years seemed rather fond of its clusters of lovely red berries, appear to be now regarding them as a last resource in the food line. In my view it is well worth a place in any garden.—HENRY A. SKETCHLEY, *Petersfield*.

IN our experience, extending over a long period of years, we have never had any difficulty with this beautiful little foliage plant as regards its hardiness. We do not remember an instance in which it suffered during winter in the smallest degree. In Mr. Nicoll's beautiful garden at Monifieth it grows like a weed, increasing in size year by year, and that without any special treatment or attention. In a cottage garden at Carnoustie we know of a huge clump growing in what is little else than a heap of small stones, where it increases with such rapidity that the owner has to curtail it every year, and here again not the least protection is given or required. Nicholson gives the native place of *T. minus* (of which

adiantifolium is a form) as the Northern Hemisphere, including Britain; consequently, if this is correct, there should be no dubiety as to its hardiness.—ALBYN.

AS you invite remarks (page 48) as to the hardness of this graceful foliage plant, commonly known as "Poor Man's Maidenhair," I beg to say that I grew it in the open border without any protection for about forty years, during which period we had as much as 20° and even 25° of frost some winters, and I never knew the plant to suffer therefrom in even the smallest degree.—CHAS. COMFORT, *Middlethian*.

PERPETUAL-FLOWERING CARNATIONS IN WINTER.

I SHALL be very grateful if any of your readers can give me a few hints on the secret of blooming Perpetual Carnations in the winter months. I have a small house devoted entirely to Carnations, and get plenty of blooms during the months from March to October, but not at this time of year, when they would be most appreciated. The house is heated, but being the end of a range of houses, the temperature does not often exceed 50°, unless it is sunny. We put our fresh plants in this house in September or October.—FLOWERS.

[We sent the enquiry to Messrs. Allwood Brothers, and subjoin their reply: "The main reason why Perpetual-flowering Carnations do not produce large supplies of bloom in mid-winter is that the plants are late-propagated stock and insufficiently matured, and invariably stopped too late in the summer to produce winter bloom. No growth should be stopped after mid-July to give good winter results; while in the case of young plants, if they receive a check from want of potting during the spring and summer, they never recover sufficiently until the following spring. In the case of plants which are, say, a year old, if these have been allowed to bloom to excess during the previous spring and summer and early autumn, they are too exhausted to give good results during the winter. It is advisable at all times to cut flowers with long stems. All Perpetual-flowering Carnations should be potted during the late spring, and if they are producing abnormal supplies of bloom, certain of these should be removed so as to minimise the strain; but what is the common mistake and, perhaps, the greatest enemy of the Carnation is the practice of using unsuitable chemical fertilisers instead of a slow-acting specially compounded Carnation food. It is very evident that a chemical food acts as a drug and quickly undermines the plants' constitution, whereas a slow-acting organic food gradually feeds and builds up the plants, so that during wintertime, when the growth is at its lowest, it feels the benefit of these plant-building properties. As to the treatment of Perpetual-flowering Carnations during winter, no house should be allowed to exceed 50° at night. If the night temperature is allowed over 50°, the plants have been forced and weakened; but even if the greenhouse is kept at, say, 45° or as low as 40°, it is essential to have some ventilation so that there is a free circulation of air. Once the air becomes stagnant the plants suffer to a marked degree."—ED.]

CHRYSANTHEMUM TOKIO.

MR. ENGLEHEART is quite wrong in saying (page 23) that I am "under some misapprehension about this variety." If he had read my note attentively he would easily have perceived, as I am sure other readers have, that I fully understand what I am writing about. Evidently he does not. Briefly, what are the plain facts? Mr. Woodall on a recent visit to the Paris Chrysanthemum Show saw "a Japanese variety called Tokyo, with tubular petals and

pretty pink colouring," as he tells us, which entirely won his admiration. Is he, too, under some misapprehension? Of course not, for there is no ambiguity about his statement, which is perfectly definite. It so happens that I also saw the same variety at the same show. Both Mr. Woodall and I are in complete accord that we are discussing one and the same variety. Both of us have seen it: Mr. Engleheart has not. That being so, it must be patent to every reader with a logical mind that if there is any misapprehension it is certainly not on my part. The identity of the flower has not been called into question until Mr. Engleheart appears on the scene with his forty-year-old red Tokio "of the strictly decorative class." After my long and varied experience in Chrysanthemum matters at home and abroad, Mr. Engleheart's criticism of my note in THE GARDEN for December 30, 1922, makes me wonder whether I am drifting towards the verge of such floral incapacity as not to know the difference between a pink tubular-petalled exhibition Japanese Chrysanthemum and a small

that the old red To Kio, a mere decorative variety, was raised by Simon Delaux anterior to 1882; the precise date cannot be determined satisfactorily. It was introduced into this country somewhat about that date. The pink Tokio, the subject of this discussion, was raised by Vilmorin and distributed in 1905, as already stated by me. Like many other French show varieties, it was never introduced into English collections, for reasons previously given.—C. HARMAN PAYNE.

THE ROBINIAS.

AMONG the flowering trees of considerable decorative value, the Locust Trees, or False Acacias, occupy an important position. They are good town trees and thrive in light, sandy soils.

The most important species and varieties are: *R. hispida*, the Rose Acacia of the South-Eastern United States, a wide spreading bush or small tree 6 ft. to 9 ft. high with large rose-coloured flowers. The variety *macrophylla* (syn. *inermis*, *Carmel*), has larger leaves and flowers, and

THE ROSE ACACIA, ROBINIA HISPIDA.

red Japanese of mere decorative merit. The only point at issue between Mr. Woodall and me is that he apparently thought that Tokio (or, as he spelt it, Tokyo) was a novelty, whereas I, on the other hand, adduced evidence to prove that it was an old one of many years standing. I was discussing a particular case, not a hypothetical one. That this variety is a pink tubular-petalled Japanese is no matter of personal taste or opinion but a pure matter of fact, and, as between Mr. Woodall and me, it has been proved by ocular demonstration. Mr. Engleheart's alternative that "possibly two varieties have been given the same name," after what has been said, must be considered to be self-evident. Such a thing has happened scores of times since Chrysanthemums began to be turned out in overwhelming numbers by the seedling raisers of the last forty years or more. It is a simple matter to verify these cases. Reference to some of the old Official Chrysanthemum Catalogues would have shewn Mr. Engleheart that To Kio (then usually written in two words) was not the Tokio under discussion. It may be useful to mention

the blooms are richer in colour. *R. Kelsey* is a bush or small tree 8 ft. or 10 ft. high, probably more in sheltered positions. With us it is the most brittle tree cultivated, and unless copiously staked and tied, winds cause frequent losses of branches. Such a beautiful tree, with its rich rose-coloured blossoms, is worth a place on a wall where adequate support can be given the branches. *R. neomexicana* flowers in June and again in August. It is a tree of moderate size from the Rocky Mountains with pale rose flowers. *R. Pseudacacia*, the Common Locust or False Acacia, is a very well known tree with its pendulous racemes of white blossoms. It would not be difficult to give fifty varietal names of the varying forms of this tree. *Decaisneana*, rose; *fastigiata*, a narrow columnar tree; and *inermis*, a small mop-headed tree, a fairly frequent occupant of small gardens, are important. *R. viscosa*, the Clammy Locust from the mountains of Carolina, is a tree of moderate size with pale rose blossoms. Failing seeds, the usual method of propagation is by grafting, using the Common False Acacia roots or small stems as stocks. A. O.

THE CULTIVATION OF THE PEACH

How to Avoid "Gumming."

WHAT are the causes of gumming in Peach trees? I know some of them, but perhaps not all. I therefore pen these lines as a feeder for those who do know.

As for prescribing a remedy, that is entirely out of my power, but I can suggest a partial preventive. We know that this malady is frequently caused by maltreatment or accident. Anything which will interrupt the vital work going on within the inner bark, is likely to cause it, and the outer bark is not sufficiently thick to bear with impunity a blow from a hammer or violent pressure from a nail or tie. We also know that the Plum is liable to suffer in this way if the stems are injured. I have a suspicion, however, that there is something in the Peach, as it is generally grown, to predispose it to gumming.

For one thing, I believe the Plum stock is too powerful and too precocious for the Peach. If you lift a young Plum tree any time and replant it before the ground becomes too cold, you will find on examination within a week or two it will have started making new roots. The chances are it would be doing the same thing if undisturbed, though perhaps to a more limited extent. It is possible that a Peach on its own roots would not do so, though I cannot prove this. I planted some young ones on their own roots some years ago with the object of testing this matter, but had to leave them behind me before the result was apparent. Does the early starting of the Plum stock cause too much and too early an impetus to the Peach? Growing roots cannot be of much use to a plant without leaves, any more than feeding an animal without digestive organs, and it is possible that such early starting of the roots is a disadvantage. Would it not be worth while, if you must have fan-trained trees, experimenting with a less vigorous and less precocious stock, such as the Sloe or Wild Bullace?

I am of opinion that the origin of gumming frequently occurs long before the malady shews itself. Just imagine what happens when a maiden tree has made a vigorous stem. For the formation of a fan-trained tree it must be cut down. This happens after the leaves have fallen and frequently after the roots have started afresh. What then becomes of the liquid matter taken up by the roots? We cannot imagine them growing without taking in something, if it is only water. I am aware that the Peach buds can scarcely be said to remain dormant, excepting in very cold weather, but their appetite is not large, and I think it is quite possible that the predisposition to gumming takes place, even at this early stage. Then at the end of the second year the young growths are cut back again, when they are frequently of irregular size and must be manipulated accordingly. This gives another step forward for the malady.

As partial confirmation of this theory, I may mention that I have grown many trees without any severe cutting and that gumming was unknown excepting from accidents or maltreatment, but in addition to the "non-but-hery," the trees were hit every year late in the autumn. This had the effect of retarding considerably both roots and buds. A fortnight's delay in the time of flowering of outdoor trees in this fickle climate often makes all the difference between a full crop and no crop. It also lessens the liability of a severe check on the constitution of the tree itself.

Why grow fan-trained trees at all? It is the most unnatural system we can adopt. No three branches have the same angle, there being

every possible elevation between horizontal and upright, and we know that those nearest the upright have the advantage. Even the Pear, which is much harder than the Peach, rebels against this system, and the lower branches of a fan-trained tree, being horizontal, never do so well as the more elevated ones. Of course, we know that being near the ground they are more liable to suffer from cold, but this does not account for all the difference. I have not planted a young fan-trained tree during the last half century, though I have shifted some middle-aged ones.

Some very nice pictures on paper have come under my notice and I have seen some of the best trees in the country grown on this system, including those trained by the great pomologist, Mr. Robert Thompson, indeed, I helped to manipulate them, and others were seen at Longford Castle, trained by Mr. H. W. Ward (who wrote a book on the subject), and afterwards well cared for by Mr. Tucker, but nowhere have I seen a perfect middle-aged tree. It is a difficult subject to teach and qualified gardeners seldom take the trouble to shew their young men how to do it, finding it much easier to do the work themselves. Then again it takes ten years to cover a 12ft. wall, even when one procures young trained trees, and that is more than the average life of a Peach grown out doors in this country.

Now having abused the time-honoured system of fan-training, what have I to offer in its place? My plan is to procure maiden trees produced on a soil which is not rich in nitrogenous matter and which in consequence are not over robust and are well ripened. These are planted 5ft. apart against a wall facing as near as possible south, in a suitable compost of loam, wood ashes, bone flour and old mortar. Four feet wide and 18ins. deep will be ample for all time, and half that width will do for the first two years. No nitrogenous manure should be used at this time. If the young trees are ripened to the point, nothing is cut off them, even the lower twigs, if there are any, and they are ripened, are left on, but any unripe growths should be removed. They will make plenty of shoots to select from during the growing season. These are to be trained on each side about 10ins. or 12ins. apart, slightly above the horizontal and have the points stopped not later than the middle of July. Some of these will fruit the following season. An important thing is to take care of the successional shoots, which every qualified Peach grower knows how to do. As soon as the fruit is gathered, the shoots which bore it are cut away, leaving the successional shoots to take their places. With the exception of disbudding—which should not be done too much at once, and not till the new growths part easily from the stem without tearing the bark—this is about all the manipulation required. This plan is followed year after year, and 18ins. on each side of the main stem is found to be sufficient for the bearing shoots.

And now I shall be expected to give some evidence of the success of this plan. Mr. John Wright, V.M.H., said, in a now defunct contemporary, "He now (1881) plants maiden trees, trims off the weak twiggy side growths, but does not shorten the leader. The trees are planted about four feet apart, the leader trained upright and the side branches herring-bone fashion." In a later note he said, "These are not crowded, as sound, stout, clean, green leafage is essential for the development of fine fruit. Every portion of a lofty wall was covered in less than four years and

the crops of fruit were over on my visit, but a first-class judge (Mr. Iggulden), who knew them well, described them as remarkable."

Three years later than the foregoing date (viz. 1884), Mr. Wright in describing the wonders of Wilton, under the management of Mr. Challis, said of the Peach trees grown in a large new house on the same plan. "They had been planted three years and every inch of the trellis was covered. . . . The fruit produced by this generous system of culture was of the first size, colour and quality." WM. TAYLOR.

SOME EARLY SALADS IN SMALL GARDENS

ALL early salads are very tender because the plants are grown without spells of dry weather coming to check progress and thus create toughness. The cultivator should, first of all, take stock of the space available—whether under glass or on the open sheltered border. In every case it is advisable to use a rich soil, even in the cold frame, where an early crop of Potatoes may be grown, in addition to the Lettuces and Radishes. Potatoes thrive in a compost made up of half the bulk of well decayed leaf-soil. The latter and some good loam mixed should be laid on a mild hot-bed to a depth of 1ft. The Potato tubers must be planted 10ins. apart in rows 18ins. asunder, with a level surface—not ridges—to receive the seeds of the Lettuce and Radish. These seeds must be sown very evenly and thinly—quite 1in. from seed to seed. Rake in the seeds and then scatter on them a thin layer of sifted soil. The Lettuces must be thinned at an early stage and used, the leaves being very succulent, and before the Potato haulm covers much surface soil the Radishes and Lettuces are all used up.

Mustard and Cress may be grown in shallow boxes in the greenhouse, or in a cold frame. Here again a rich compost is advisable. Fill the boxes level with the rims, then press down with a piece of board, water, and sow the seeds thickly, gently pressing them into the damp soil but not further covering with soil, then the resultant plants are clean and free from grit. Sow seeds every ten days to ensure a succession of young plants.

ONIONS.—Where outside Onions are scarce a pinch of seeds, sown in two boxes filled with good loam and made firm, will provide hundreds of young plants many weeks before the latter are available from open-air sowings.

CELERY.—Usually the outdoor stock of Celery is exhausted early in the New Year and a boxful of seedlings will be much appreciated for flavouring purposes. It is only necessary to cover the seed lightly and to keep the soil moist by immersing the box as required.

LETTUCE.—Seeds of an early Cabbage variety should be sown thinly in a box and placed near the roof glass; when the seedlings are quite small transplant them in prepared boxes of soil at 1in. apart and still retain them under glass. The second transplanting should be made in a rich soil on the south side of a wall or fence, the border being slightly raised; plant at 7ins. apart each way and place some sticks 1ft. above the bed to bear any light covering at first for a week or two, especially at night. Directly the young plants begin to form hearts, draw for use alternate ones; those left will attain to a large size.

TOMATOES AND CUCUMBERS.—Where fire heat is limited the cultivator will gain much valuable time by purchasing a few plants raised early in January. At this season such are not difficult to establish in their respective houses. G. G.

STORING VEGETABLES AND FRUITS,
with chapters on "Drying in the Oven and by the Kitchen Fire." By HERBERT COWLEY. 9d. net, by post 11d.—Published at the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

PAUSE TO CONSIDER

THIS SPECIAL OFFER OF CHOICE ALPINES.

Then order for Spring delivery the following plants from pots:—

SAXIFRAGA IRVINGII, the best pink Kabeschla.
ONOSMA ALBO-ROSEUM, rosy white.
SAXIFRAGA KELLERII, early pink and white spikes, 6 inches.

PRIMULA INTEGRIFOLIA, collected plants; a fine range of colours—pale to darker pink and mauve.

LITHOSPERMUM ROSEMARINIFOLIUM, a charming blue, 1 foot high.

RANUNCULUS GLACIALIS, 9 inch; collected plants, but established.

DIANTHUS ALPINUS.

SAXIFRAGA BURSERIANA SULPHUREA, pale primrose, very free.

RAMONDIA PYRENAICA, for shady places, mauve.

CAMPANULA WALDSTEINIANA, deep mauve, 4 inches high.

GENTIANA FARRERI, a gem for moraine; pale blue; from China.

ERYTHRAEA MASSONII (the pink Gentian); soft pink, 3 inches.

Carriage paid, for cash with order, for 17. 6.

Strong Hardy Climbers. **Ampelopsis**, Veitchii, self-climbing, small leaf, large roots, several trails, each 2'. **Clematis**, Traveller's Joy and Flammula (Virgin's Bower), white, rapid climbers, large two year roots, 1/9 each. **Honeysuckle**, very fine red-flowering Dutch, large plants, 2/6 each. **Wistaria** sinensis, large racemes of bluish-lilac flowers, 3/- each.

Several dozen **White Lilac**, large roots, bushy, lit., 2ft. and 2ft., 6/-, 8/-, 10/- doz. **Cataloque Free.**

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Peas.—To keep up a continuous supply of this delightful vegetable fortnightly sowings will be necessary. Peas enjoy a rich soil and plenty of space between the rows. Gradus is a good variety to sow now, and the seeds should be placed in flat drills 1½ ins. deep. A distance of 3 ft. ought to be allowed between the lines. If mice are troublesome, the seeds may be damped with paraffin and then given a coating of red lead. A watch must also be kept for birds, which often destroy the young plants just as they are coming through the soil.

Jerusalem Artichokes may be planted directly an opportunity occurs. Whole tubers should be planted 6 ins. deep in rows 3 ft. apart, allowing about 1 ft. between each tuber. If any of last year's crop are still in the ground, they ought now to be lifted and the tubers covered with ashes until they are needed for the kitchen. When digging up Artichokes care must be taken to remove every tuber, or they will be a nuisance later on.

Seakale.—The thongs prepared some weeks ago may be planted in lines 2 ft. apart and 1 ft. between the sets, covering the tops with rim. of soil. When growth begins it will be necessary to rub off all the shoots except the strongest; then the ground must be kept free from weeds. During the growing season liquid manure may be afforded occasionally, while a light sprinkling of salt twice or three times during the growing period is also beneficial.

The Flower Garden.

Begonias.—Tuberous-rooted Begonias that are to be used for bedding should be placed closely together in shallow boxes with a little leaf-soil and sand sprinkled between the tubers. A warm greenhouse or vinery will be needed to start them into growth, and when the shoots are visible the large tubers may be divided and the cut portions dusted over with lime. Each piece should possess at least one shoot or growing point. A little seed ought to be sown each year, and if this is done now nice plants will be produced to take the place of losses next season. Pots of fine soil should be prepared, and when the seed is sown no covering of soil will be necessary if the receptacle is given a sharp tap near the rim. Cover the pot with a sheet of glass and place in a temperature of 65° to 70°. When the seedlings are large enough to handle prick them off in boxes, where they will make fair-sized tubers, while many will produce flowers. Begonias thrive in a compost consisting largely of good quality leaf-mould and sharp sand, and it ought not to be packed too tight around the tubers.

Lily of the Valley.—After a period of three or four years these lovely plants become too crowded to produce strong flower-spikes, therefore it is necessary to replant a portion of the plants each year. The new ground should be dug deeply, liberally manured and a moderate supply of leaf-mould incorporated as the digging proceeds. Lift the old plants, select the best and strongest crowns, and replant them 3 ins. or 4 ins. apart. A partially shaded position is best for these chaste and beautiful "Lilies."

Fruit Under Glass.

Vines that were started a month or two ago will require attention in regard to the tying and pinching of the shoots. These must be brought down to the wires gradually, and where the spurs are old two or three tyings will be necessary, as the growths, being very brittle, are easily broken. Each shoot will require pinching, and the centre should be removed at the second or third joint beyond the bunch of fruit. Growth not bearing must also be pinched, but here the amount of space to fill must be taken into consideration and the shoot stopped accordingly. Vines that are growing freely should have a night temperature of 60° to 65°, with a rise of several degrees during the day. The atmosphere should be kept moist and a little ventilation given when the sun is bright. This is essential or the foliage may be scorched and irretrievably ruined. Early in the afternoon the floors and walls should be sprinkled with water and the ventilators closed to secure as much sun-heat as possible. When the plants are in bloom the atmosphere should be kept on the dry side and the rods tapped daily to distribute the pollen. Watering the roots must receive attention, and well rooted Vines in a properly

drained border will take a copious supply until the Grapes are well advanced.

The Hardy Fruit Garden.

Raspberries.—The old canes were no doubt cut out at the end of the fruiting season, and now it will only be necessary to remove a few canes where they are too thick. The supports should be examined, and where the posts have decayed they should be replaced. If the supports are barked and the bases given a coating of tar, they will remain in a sound condition for a long period. Tie the canes to the wire supports and lightly fork over the soil between the rows. A mulching of leaf-mould and decayed manure will be beneficial.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Rhubarb.—If established plantations did not receive a dressing of manure in autumn, a liberal one should be applied now, and in either case the ground between the stools should be forked over. The manure should be half decayed.

Celery.—As the Celery crop will be getting well through, the cleared ground should be deeply dug. The site of each trench makes an ideal site for a row of Peas, and if this suggestion is adopted it will be unnecessary to apply any manure.

Chives.—These provide an excellent substitute for Onions in spring before young Onions become plentiful. Established clumps of Chives may be broken up now and transplanted into rich soil.

Spinach.—If the soil is in fairly dry condition, apply a dressing of soot, dry fowl manure or nitrate of soda, and hoe it in with the Dutch hoe.

The Flower Garden.

Herbaceous Plants.—Weather permitting, new plantations may now be made. In breaking up established clumps the outside parts should be selected for planting, as they are the most vigorous. All the beds or borders of this class of plants should be dug over, and if there are blank spaces left for half-hardy plants later on, these should be more deeply dug than the quarter generally.

Early Sweet Peas.—Autumn-sown Sweet Peas intended for flowering in June should be shifted into 6 in. pots and be staked with dwarf, twiggy stakes, beech for preference. Keep the plants cool and well exposed to the light.

Bulbous Anemones should now be planted as soon as the state of the ground will permit. A light, well drained soil is necessary for their successful cultivation, and where the natural soil is heavy it should be improved by the addition of sand or old potting soil. Plant about 2 ins. deep. In the event of keen frost setting in, some protection must be afforded the plants. The foregoing remarks are also applicable to Ranunculi.

Climbing Roses should now be pruned as they start into growth early. A good deal of autumn pruning may have been done among the ramblers, but the operation should be completed now. As far as possible the old shoots should be cut away and the best of the young shoots retained. If the latter are deficient, some of the healthiest of the old should be retained.

Fruit Under Glass.

Early Vines.—Continue to tie down the laterals and stop them, leaving two joints beyond the bunch. Stop all sub-laterals beyond the first joint. If two bunches appear on the same lateral, the weaker of the two should be cut away. Over-cropping generally must be guarded against.

Melons.—As solar heat and light are now on the increase a sowing of Melon seed may be made. Sow the seeds singly in small pots three-quarters filled with pure maiden loam and plunge in bottom heat. Maintain a temperature of from 65° to 70°, and utilise the sun-heat as far as possible at this stage. Hero of Lockinge (white flesh) and Munro's Little Heath (scarlet flesh) are suitable varieties for present sowing, both being good setters and bearing medium-sized fruits.

Tomatoes.—Plants should be shifted into 5 in. pots, using only a moderately rich compost. The aim should be to build up plants with firm stems and short joints. Expose to full light.

The Pleasure Grounds.

Walks and drives should be kept clean by means of the hoe and rake. They should be gone over whenever weather permits to check

the seedling weeds which are lying dormant and all but invisible.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Buddleia asiatica should now be propagated by means of cuttings, using half-ripened twiggy shoots for this purpose. The cuttings should be inserted in pots containing sandy soil and plunged in a close case with slight bottom heat at command. This plant is sometimes troublesome to propagate from cuttings, but little trouble should be experienced if slender, twiggy growths are selected. They should make good plants in 6 in. pots the first season, and these are useful for furnishing the stages in the conservatory. After flowering the plants should be pruned back and grown on into 8 in. and 10 in. pots, in which they should in their second year make fine specimens 6 ft. to 8 ft. high. During the summer they should be plunged outdoors in an ash bed, as this helps to ripen the wood and ensures free flowering during the winter. This is a very elegant plant, and produces its long, slender sprays of fragrant white flowers very freely. If only for its delicious perfume this plant should be more generally grown, for although introduced in 1874, it is by no means a common plant in gardens. It grows freely when planted out, and is very fine for clothing pillars in a large cool house.

Buddleia officinalis is a later introduction from China and has dull lilac-coloured flowers with a yellow eye. It is a stiff-growing shrub, easily propagated from cuttings and, like *B. asiatica*, flowers during the winter months. Although it does not possess the grace and charm of *B. asiatica*, its strong honey-scented flowers appeal to some people. This plant succeeds quite well under the cultural conditions indicated for *B. asiatica*.

Asclepias curassavica.—This is a useful and showy plant for conservatory decoration, as it lasts in flower for a very long time. If seed is sown in a warm house at this time, the resultant plants will flower during late summer and autumn. As it is a slender-growing plant, the best results are obtained by potting off four seedlings into a small sixty-sized pot, afterwards potting them into 5 in. pots, in which they should flower. They should be allowed to grow straight on without stopping. These plants only require an ordinary greenhouse temperature, and will grow quite well in any ordinary potting compost. This is a free-rooting plant, and when the pots are well filled with roots frequent applications of diluted liquid manure should be given. If desired, the plants can be grown on for the second year.

Cannas in 6 in. or 7 in. pots are very useful and showy plants for furnishing the stages in the conservatory during summer and autumn. Strong rhizomes should now be selected and trimmed to a suitable size to go into 48-sized pots, using a light rich compost for them. They should be stood in a warm house with a temperature of 60° to 65°, and should be given very little water until they start into growth and have made a quantity of roots. This is very important, for if overwatered at this stage they are very apt to decay. When growing freely and the pots are well filled with roots, they should have a shift into 7 in. pots, using a very rich compost, as they are gross feeders. As these pots become well filled with roots plenty of diluted liquid manure and soot water should be applied. Cannas grown in this way should have growth restricted to a single shoot. By growing successional batches a display of bloom may be had until well into autumn. Large specimen Cannas are very useful for standing on beds in the conservatory. Where such are required they should be made up early next month, putting several strong rhizomes into 10 in. or 12 in. pots, leaving room to give a good top-dressing. Given generous treatment such plants keep up a good display until Chrysanthemums come in.

Sollya heterophylla.—This twining Australian plant with its beautiful blue flowers, which are produced in wonderful profusion over a long period, is one of the most charming of our cool greenhouse plants, as also is the smaller *Sollya parviflora*. They make pretty pot plants with the growths neatly tied to slender stakes; but are seen at their best when they can be planted out in the conservatory and trained over a trellis or up a pillar. They can be propagated from cuttings, but the plants usually ripen plenty of good seed, which affords a ready means of increase. They grow well in a light loam with a little fibrous peat added.

Royal Botanic Gardens, Kew.

J. COUTTS.

The Pearl Bush (*Exochorda grandiflora*) is a fine shrub which is not accorded the attention it deserves. The majority of amateur gardeners who grow its near relations, the shrubby *Spiræas*, seldom seem to include it in their planting lists, yet it is in its own way a more strikingly handsome shrub than any of its allies. *E. grandiflora* (syn. *Spiræa grandiflora*) is a hardy, deciduous shrub which forms a large bush, some 8 ft. to 10 ft. in height, of slender branches which droop over in a most elegant manner. The foliage is of a delightful shade of emerald green, the comparatively large leaves being of a soft and delicate texture. Soon after these have appeared the ends of the pendulous branches become adorned with long sprays of pure white, fragrant blossoms, each of the latter being about 1½ in. in diameter, so that a well grown bush of *E. grandiflora* is most attractive. Almost any soil that is not too dry will suit this plant, but it enjoys a warm, generous loam and a sheltered situation with full sun. This splendid shrub can be obtained quite cheaply and, once planted, it will carry on for years without any attention whatsoever.

A Charming Alpine.—There are some plants which, no matter how well known, are able to hold their own against any rivals, and one of these is *Hutchinsia alpina*. For a cool spot in the rock garden, the shady side of steps or other place of the kind, this little plant is admirable, perfectly easy to grow and never demanding any attention. From its spreading mat of fern-like foliage *H. alpina* sends up in May a large number of 2 in. to 3 in. stems, each of which terminates in a loose cluster of milk-white flowers, which will remain fresh and cheerful right on to full summer. Though a good many of our smaller Cruciferous plants in white are apt to be unsatisfactory, if not a little mean, *H. alpina* more than escapes that opprobrium the colour and character of its foliage, no less than the purity and density of its whiteness, together with its cheerful nature, doubtless raising it above the commonplace. In some gardens a patch of *H. alpina* is made to serve as a carpeting for the lesser *Narcissi* and other little bulbous plants with good effect.

An Alpine Daphne. The lovely *Daphne Blagayana* opens its ivory-white, lily-scented flowers in the early part of the year and is usually still in bloom to greet the spring. *D. Blagayana* is a true alpine and quite hardy, a creeping plant of lowly stature which delights in a rocky bed of rather cool, vegetable soil mixed with grit. Though many fail to grow it satisfactorily it is not really difficult. It generally succeeds best in a half-shady aspect, but some excellent specimens have been grown with full exposure. Having planted *D. Blagayana* in such a bed as described above it is advisable to place pieces of rock or stone about the size of half a brick on the surface between the prostrate branches. As the latter develop they may be top-dressed occasionally with leaf-mould, grit and loam, the largest being layered by placing a stone just behind the terminal leaf-tuft. More stones and compost are added from time to time so that the plant will ultimately be established in a sort of low cairn.

United Horticultural Provident Society. Mr. Thomas Winton, who for the past ten years has been Treasurer of the United Horticultural Benefit and Provident Society, having tendered his resignation owing to very serious illness, Mr. Arthur Bedford of Gammersbury House Gardens, Acton, has been duly elected Treasurer, pro. tem., at a special meeting held on February 7, 1923.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

EDGING AND OTHER PLANTS FOR FLOWER BEDS (J. G.).—As an edging to the Antirrhinums, *Viola Snowflake* would be suitable. For the other bed we think *Clarkias*, pink and white, or white and red, would look better than the three colours together. The *Schizanthus* Dr. Badger's hybrids, with an edging of *Silene Empress of India*, would look well, but a *Viola* would last longer in bloom than the *Silene*. The golden-leaved *Thyme*, *Thymus citriodorus aureus*, makes a charming edging. The *Iberis*, to which our correspondent refers, is probably the perennial *Candytuft*, *Iberis coraeifolia*, pure white, compact, bearing flowers in profusion.

IPOMÆA RUBRO-CERULEA AND ADONIS (R. C.).—The *Ipomœa rubro-cerulea* should be treated as a half-hardy annual. There should not be any difficulty in raising the seedlings if treated similarly to *Asters*, for instance. Warm positions are best. The plants flower profusely in pots in a cold greenhouse. Some should be so grown till they are in 6 in. pots, then transferred to 8 in. and the pots plunged to the rims in the outside border in May. Use only a medium rich compost. It is quite possible that the seeds were not properly matured or were in some way damaged in the case of the *Adonis*. If more are sown, place the pan in a cold frame and use a good compost in which some pounded brick and coarse sand has been mixed. Water by immersing the pan; shade from the sun's rays. Cover the pan with glass.

WATER LILIES UNSATISFACTORY (W. M. G.).—Our correspondent did the right thing in planting the Lilies in baskets, but the latter should rest on mounds of loam at the bottom of the concreted pond. It is not necessary to cover the whole of the bottom, a space about 2 ft. 6 in. square for each basket being sufficient. Lumpy, fibrous loam in which the grass roots are dead is best; add a small quantity of decayed cow manure and half-rotted leaf-mould respectively to a depth of 6 in. or so. *Nymphaeas* like the sun and succeed best in rather still water, but some fresh should trickle in frequently, if not daily. The best months for planting are April, May and June.

TREES AND SHRUBS.

PRUNING SHRUBS ON WALL (A. M. Kent).—All three shrubs named should be pruned as soon as flowering is finished. This would mean about March in the case of *Lonicera fragrantissima*, April for the *Forcythia* and May with *Pyrus japonica*.

THE WILD BROOM ("Summer").—The Wild Broom (*Cytisus scoparius*) is not an easy shrub to transplant. Nurserymen usually cultivate plants in pots for sale so that planting could be done at almost any time. It is readily raised from seeds. An alternative shrub we suggest is *Cistus cyprius*. This is evergreen, thrives in most soils (except wet clay), and produces quantities of white blossoms in summer. *C. cyprius* is also cultivated in pots, not being easy to transplant.

SINGLE LILAC (A. J. B.).—The variety *Princess Marie* has very pleasing lilac-pink blossoms and is fragrant. This may be the variety noted by our correspondent, but the named sorts are now very numerous. Perhaps it was the variety *Mme. Francisque Morel*, which has very large thyrses, but we should describe the colour as violet-pink rather than lilac-pink.

THE GREENHOUSE.

THE NAME OF A SMALL-FLOWERED NICOTIANA (M. C. M.).—The small white-flowered *Nicotiana* referred to by our correspondent is, undoubtedly, *Sutton's Miniature White*, which grows to a height of 18 in. and forms a lovely pot plant for the greenhouse. It is very sweet-scented.

FORCED RHUBARB UNSATISFACTORY (W. E. T. Sussex).—There is no fungus or other obvious cause of disease in the Rhubarb stalks sent for examination. There may, however, be disease, as our correspondent suggests, in the stools, but that we cannot ascertain without careful examination of them. Possibly the conditions are too dry for the work of forcing the plants.

ROSE CULTURE UNDER GLASS (W. R. Y.).—"The unheated span-roof greenhouse, 30 ft. by 10 ft. by 8 ft., to the roof-ridge, open sunny position, ample ventilation," will be quite suitable for Roses. Overcrowding must be avoided and the better plan would be to have some plants in pots, reserving a place for these. The border plants will flower several weeks earlier than those outside so that the retarded pot plants will prolong the supply of blossom considerably. If a few plants of *Hadley*, *Emerson*, *Molly Sharman*, *Crawford*, *Mrs. H. Stevens* and *Mme. Abel Chateaux* be included in the collection, it will be possible to have some Rose blooms seven or eight months out of the year if the flowers are cut regularly with fairly long stems. Green aphids will be troublesome; the use of Antioch-red will clear the plants of these and "Abol" will be beneficial in the case of mildew. If necessary, we should not hesitate to use these for the purposes named.

CÆLOGYNE CRISTATA (H. E. S.).—This plant usually produces its flowers from February to April, and immediately after blooming the plants make their season's growth. The pseudobulbs of *C. cristata* often present a slightly shrivelled appearance, which is not detrimental unless it is caused by loss of roots. This *Cælogyne* does not like repotting, and after being disturbed it takes two years for the plants thoroughly to recover. Our correspondent's plants are evidently starved, and we should feel inclined to cut away a few of the old pseudobulbs and then pack pieces of peat or osmunda fibre

between the bulbs without taking the plant out of its pan. During the growing period a warm greenhouse is essential, one where the temperature does not fall below 55° Fahr., the plants being shaded from all strong sunlight. Water should be given liberally while the plants are growing, but directly the new pseudobulbs approach maturity a less quantity will suffice. A short rest should be allowed, the soil being kept just moist, and this treatment continued until the plants have flowered. The flower-spikes are produced simultaneously with the new growth, so care must be taken to prevent water resting in the young shoot, or the scape will perish. This is sometimes the cause for the non-appearance of blooms.

DENDROBIUM NOBILE (H. E. S., Ramsey).—This Orchid under ordinary conditions should flower from January to March. When the flowers are over the new growth will soon form roots at the base, and when these are seen any repotting or top-dressing may be done. When repotting ordinary flower pots or pans should be filled one-half of their depth with drainage material, and the rooting medium should consist of peat or osmunda fibre and just a sprinkling of sphagnum moss with the last layer of fibre. Do not overpot, but make the soil fairly firm, while the pseudobulbs will probably need a thin stake to hold them in position. The plants ought now to be placed in a warm moist house where the temperature does not fall below 60° Fahr. A cucumber-house, stove orinery is suitable. Afford water in moderation until the roots have taken possession of the soil, then a liberal quantity can be given until the pseudobulbs are fully matured. Shade the plants from hot sunshine and keep them fairly near the roof glass. When the season's growth is completed less water is needed, and a vinery from which the fruit has been gathered will be an excellent place for them to ripen their pseudobulbs. Now follows the resting period in a temperature of 50°, where the atmosphere is dry and only enough water is given to maintain the pseudobulbs in a plump and rigid condition. Annual repotting is not needed, and provided the plants are treated correctly in regard to watering, once in three years will be ample.

FRUIT GARDEN.

APPLES SHRIVELLED (E. H. J. Putney).—The Apples are past their season, and are not only shrivelled but beginning to decay. They should be allowed to hang until they part easily from the tree, and they might then be kept well wrapped in paper.

VARIETIES OF NUTS TO GROW (G. A. S.).—Our correspondent cannot do better than grow the Spanish Chestnut, the nuts are sound, when matured and very sweet. The *Kentish Cob* is always reliable and very generally grown. If large trees are desired, the Common Walnut is the best. A variety named *Fertilis* is very dwarf-growing in comparison and fruits when the trees are quite young, and this is worth growing also. There would be room for both varieties, the last named, though the nuts are smaller, is very prolific.

MISCELLANEOUS.

ABOUT STORING APPLES (B. M. B.).—The early varieties of Apples if allowed to become ripe and fall off the branches easily, do lose much flavour and get quite mealy. Late sorts should be well ripened when gathered then they retain their freshness for a long time, not shrivelling if not wiped with a cloth. Our correspondent seems to have treated the fruits correctly in the store. Very choice specimens merit the trouble entailed in wrapping each one in grease paper. If the Apples are peeled, sliced and placed in cold water for twelve hours they will plump up and be improved for cooking. Many early and mid-season sorts failed to keep satisfactorily in autumn and early winter. They lacked sunshine!

TO DESTROY WORMS ON LAWNS (E. M. S.).—Preparations for this purpose are sold by seedsmen and horticultural sundriesmen, who also supply directions for use. A cheap and fairly effective remedy may be made at home by placing a bushel of lime in a tub containing sufficient water to make a thin solution when stirred. Allow the time to settle down, then use the clear liquid, adding to it an equal quantity of clear water. Apply freely through a rose watering-can. The worms will come to the surface.

NAMES OF PLANTS.—J. S., Dumbartonshire.—1. *Ilex Aquifolium* var. *flavescens*; 2. *Osmanthus Aquifolium*; 3. *Quercus glabra*; 4. *Ruscus Hypoglossum*; 5. *Pulmonaria rubra*.—A. T., E. Yorks.—*Cotoneaster frigida*.—H. P., *Ligustrum japonicum*, "Japanese Privet."

"That's the kind of garden I'd like"

"Strong hardy plants, flowering nearly all the year round as fine a bed of vegetables as you'll find within a few miles, and fruit trees that never fail. I can't get anything like the same results in my garden."

But you can. Use **ECLIPSE** Fish Manure and you will think a minute. Realise that you're starving your plants and trees. The soil is poor. It gives insufficient nourishment. It lacks certain essential properties without which plants cannot thrive. Enrich the soil with **ECLIPSE** Fish Manure — and you'll get harder plants, a profusion of deep rich-coloured blooms and a good crop of fruit and vegetables, year after year.

ECLIPSE Fish Manure contains Phosphates, Nitrogen and 1 otash in their proper proportions. Being largely organic, it supplies humus to the soil.

[FEBRUARY 24, 1923.]

FLOWERING EVERGREEN SHRUBS

THERE is no need to point out to a practical gardener the importance of evergreens in the garden scheme. There is, indeed, a regrettable tendency in some quarters to use them in unsuitable places. There was a time—not so very long ago—when it was considered proper to clothe the table legs. This attitude we very properly deride, yet, even to-day, one often sees the butts of fine forest trees obscured by meaningless evergreen planting. Such planting effectively destroys the balance and grace which, with the appearance of strength and solidity, constitute the charm of a well grown tree.

We digress. The value of evergreen shrubs admitted, there seems no reason why a much greater proportion of those used should not be flowering shrubs than is at present the case. There are very few positions where the fact that a shrub at some period of the year bears attractive flowers (or handsome fruits) is a disadvantage.

Yew and Holly, each in its particular way, are, of course, admirable hedge plants. They also have decorative value as trees. Laurel has none of these advantages. It is an unsatisfactory permanent hedge and, as usually seen, cumbered ground which might be occupied by more beautiful, as well as more interesting shrubs.

If a substitute be sought with something of the same leaf character, there is a multitude of hybrid Rhododendrons to choose from, to say nothing of the ever-swelling legion of large-leaved species. The so-called American Wood-Laurel, *Kalmia latifolia*, is also charming when in flower and valuable as flowering when the bulk of Rhododendrons are over, though the Rhododendron season, with new introductions, grows steadily longer. A fascinating topic! but one we must not on this occasion pursue, for this is not an article on Rhododendrons. On soils with an appreciable lime content these Rhododendrons will not grow, but large-leaved flowering evergreens are still to be found. We have the so-called Strawberry Trees, for example, *Arbutus Unedo* and its varieties, *A. Andrachne* and the hybrid between the two species, *A. hybrida*, none of which objects to lime. *Cistus laurifolius* is also worthy of

mention, since it forms a good solid background when out of flower though, of course, its leaves resemble the Laurel only in shape—not in size. It is a most attractive shrub when in flower.

The same may be said of the large-leaved Escallonias which, on well drained soils, are much more hardy than many people suppose. The two hardest large-leaved species are *EE. macrantha* and *rubra*. Of these two *E. rubra* is usually considered the hardier, but, in the writer's opinion, this is exceedingly doubtful. *E. punctata* is handsomer than *E. rubra*, but scarcely so hardy, yet it is an invaluable species for the southern edge of woodland, or for sheltered sites generally, in

any but the coldest districts. *E. Ingrami* might be described as a smaller form (in leaf and flower) of *E. macrantha*. *E. illinita* is a white-flowered species not often seen in gardens, and comparatively hardy. It is noteworthy mainly for the odour which the leaves give off and which is unusual, but not specially pleasing. It has, indeed, been compared to that of a pigsty! Two other large-leaved, white-flowered species are worthy of mention, but, unless on a wall, they are only hardy near our seaboards. These are *EE. floribunda* and *montevidensis*. The *Laurustinus*, *Viburnum Tinus*, is not everybody's shrub, but it is certainly preferable to any of the true Laurels (*Prunus Laurocerasus* and varieties). It has, moreover, the very great merit of flowering in winter.

For association with these shrubs of comparatively large and distinctly glossy foliage, we have a considerable choice of species with entirely different but characteristic leafage. We have a number of very beautiful Barberries, for example. There is *Berberis Darwinii*, with glowing orange lanterns in spring and blue-black fruits in early autumn, or its hybrid, *B. stenophylla*, rather less telling in colour, but more graceful in mien. Then again, we have *Berberis buxifolia* (*dulcis*), less gorgeous no doubt, but displaying its beautifully-shaped golden lanterns to great advantage. Very distinct, again, is Hooker's Barberry, *B. Hookeri*, which, in gardens, is generally known as *B. Jamesoni* or *B. Wallichiana*. This has relatively large foliage—up to 3 ins. long—in tufts, black green above, glaucous white beneath. The flowers are relatively large, but not very showy, sulphur yellow in colour and the blue-black berries long and cylindrical. There is a taller, larger growing form of this known botanically as var. *latifolia*, but in gardens as *Berberis Knightii*. Seedlings raised from seeds of the type species not uncommonly come without the whitish under-surface, resembling to that extent the variety *latifolia*, which has foliage green beneath. The green-leaved variety of the typical plant is known as var. *viridis*.

Then we have the broad-leaved Barberries which to most of us are still "Mahonia." There is the old favourite Oregon Grape itself, *Mahonia*

PRACTICALLY AN EVERGREEN MOCK ORANGE, *CARPENTERIA CALIFORNICA*.

Apocynum, invaluable for underplanting and now largely used for game coverts. Then there is *Berberis japonica* and its several varieties including the one generally listed as *B. Bealei*, *B. nepalensis* and *B. nervosa*.

There are several useful evergreen *Cotoneasters*—such, if of small value as flowering shrubs, are admirable when in fruit. These include *C. Francheti*, *pamosa*, *luxifolia*, *salicifolia* (and varieties), and *tubinata*. Of prostrate sorts *C. microphylla* and *Danienii* are reliable and beautiful fruiting shrubs. All the *Pyracanthas* are also delightful fruiting evergreens.

There are several beautiful small-leaved *Escallomas*, most of them of hybrid origin. Specially worthy of mention are *langleyensis* (*macrantha* Philippiana), *Donard* Seedling and *edmonsi*.

Of evergreen *Ceanothuses* the only one likely to succeed in the open inland without considerable protection is *Ceanothus thyrsiflorus*, the so-called Californian *Blue*, which in time reaches the stature of a small tree. The flower trusses, which are of fair size, are pale blue. The variety *griseus* is almost as hardy. It has much larger foliage, is a quicker grower and the blossoms are pale lilac. Moderately hardy, too, is *C. Lobbianus*, now considered to be a natural hybrid between *C. thyrsiflorus* and *C. dentatus*. This is a bright blue flowered kind, often seen in gardens as *C. dentatus*. This muddled nomenclature leads to much confusion as to the hardiness of various families of plants which are not, in general, entirely hardy.

The Mexican Orange, *Choisya ternata*, is unquestionably far harder than most people consider it. Given shelter from wind & frost it will withstand very low temperatures unharmed. Its beauty none will deny. The *Raphiolepis* has the same highly glazed foliage as the *Choisya*, but in general appearance these shrubs remind one more of the *Escallomas* than anything else. The two hardiest species are *R. japonica* and *Delacouri*, the former with white and the latter with pink flowers.

That beautiful and fragrant relative of the Mock Orange, *Carpentaria californica*, requires a wall in most districts, though it makes a beautiful shrub in the open on our western seaboard. It flowers about mid-summer, a time when shrub-flower is welcome. The same may, with equal truth, be said of *Garrya elliptica*, though it certainly resembles the *Carpentaria* not at all. The handsome catkins in this case are at their best in the depth of winter.

Rosemary and Lavender used once to be in every garden. Alas! they are so no longer, yet both are admirable evergreen (or rather ever-grey!) shrubs, and the latter is really beautiful, as well as fragrant, when in flower. There is now much variety obtainable in Lavenders, the true Lavender, *Lavandula vera* being obtainable in pale and dark forms, as well as in forms of varying degrees of compactness.

There are, of course, many beautiful American plants still unmentioned, notably those of the *Andromeda* clan—such as *Pieris japonica* and *P. floribunda*—and *Leucothoe Catesbei*, besides the Heaths. Tall varieties of the latter which are very effective include *Erica australis* and *E. arborea* (and variety *alpina*), *lusitanica*, *mediterranea*, *Veitchii* and *stricta*.

Shrubby *Veronicas* are numerous, but many of them are too tender for any except favoured gardens. *V. Traversii* is probably the hardest, but though a useful, it is not a particularly interesting shrub. The smaller, *V. luxifolia*, is choicer looking though less free to flower. *V. anomala* is free-flowering and quaint though it tends to get lanky and leggy with age. *V. salicifolia* is one of the hardest as it is one of the handsomest of *Veronicas*. In the best and hardiest form the flowers are practically snow white, but there are purplish forms.

FOR SUN OR SHADE, BERBERIS STENOPHYLLA

BLOSSOM OF ARBUTUS ANDRACHNE.

THE LAVENDER WALK AT WARLEY PLACE.

A SELECTION OF TRAILING PLANTS

WITHOUT putting too fine a definition on the term, one may indicate a goodly number of trailing plants of easy culture whose lowly stature and habit of quickly draping bank or boulder commend them to a wide variety of uses. Among these the genus *Vinca* (Periwinkle) must take a foremost place, a place that some members of the family might claim by right of precedence on the grounds that they can always be relied upon to bloom during the first few weeks of the year. With the exception of *V. major*, which is too rampant for anywhere but the wilder parts of the garden and shady spots where few other things would exist, all these are useful and delightful little plants. One of the most charming is the old form of *V. minor* with round, creamy-white flowers and gold or silver variegated foliage, this being a most profuse blossomer through spring and the early part of summer. The deep purple, varying to rose, is also attractive and hardly less free, and there is a clear white variety with very starred flowers and deep green foliage which is admirable on a shady woodland bank. These white forms sometimes produce curious reversions to the type, the flowers being marked with triangular patches of blue-lavender. In the latter colour there is a pretty double, a strong and vigorous grower, first-rate for shrubbery and woodland; another single one, a deep blue known as "Bowles' Variety," is distinct and good. After these, in order of flowering, comes *V. herbacea*, which completely vanishes, leaf and branch, in autumn, to re-appear in spring and send its long, thin stems creeping over rock or soil. Though a most useful and desirable species, *V. herbacea* must be grown in a considerable mass before one can realise Mr. Farrer's enthusiastic description of its blue, starry flowers. Here, at any rate, it seems to fail just before the moment of triumph, so to speak. Possibly it may need lime, or crave for some other essential which our soil does not provide.

The *Lithospermums* include some admirable trailers, both *L. prostratum* and its variety "Heavenly Blue" covering large areas with their deep green foliage and charming flowers. Where it succeeds, *L. purpureo-ceruleum*, a native species, is also first-rate and one that will adorn its arching runners with sprays of sapphire in places too shady for most things. Earlier with us, but not so with all, is that other sprawling member of the genus, *L. Zollingeri*, whose flowers in pale blue are not less beautiful than those of our Welsh representative just alluded to.

Helichrysum trinerve is sometimes described as a large edition of *H. bellidioides*, but it is more truly a trailer than that well known carpeter. *H. trinerve* is an evergreen perennial whose wine-coloured branches will crawl 18 ins. or more, while it turns up at intervals one of its willow-like leaves as if to shew the white downiness of its underparts. This is such a hearty grower that a root of it looks like holding its own with two other excellent trailing plants, viz., *Arenaria montana* and the Creeping Jenny, *Lysimachia Nummularia*, both of which possess a "grandiflora" form which is incomparably better than the type.

The clan *Veronica*, of course, affords us a wide assortment of plants and lowly shrubs which might come within my scope here, but I must be content to mention a few of our first favourites. *V. chathamica* is a very delightful little shrub, with pea-green leaves and wiry stems, which will, like Ivy, veil the face of a rock. It adorns itself towards the latter end of summer with pretty lavender flowers. Both the rose and the blue forms of

V. pectinata are very appealing, and they will cover a bit of poor, stony ground with thick mats of downy foliage as prettily as most things. The best forms of *V. rupestris* (*V. Teucrium* var. *dubia*) are excellent in colour and robust, the golden-leaved, blue-flowered variety listed as "Trebane" being one of the most noteworthy. *V. rupestris* in white and the even more uncommon rosy-pink variety are both admirable. *V. cinerea*, with trailing cushions, grey-green and downy, and lively pink spikes towards the summer's end, must also be mentioned here.

Muehlenbeckia complexa is a sturdy evergreen trailing plant which can be useful in large rock-gardens or even among shrubs. Its ebony branches, however, are apt to appear stiff and woody as soon as they get off the flat, which they seem to prefer, and for this reason many would rather have the much more amenable variety "nana." Still more attractive in some respects is *M. varians*, with

habit, and *C. schipkaensis* is another of this class which is very distinctive, since it carries its creamy-white flowers in circular heads. *Genista* gives us among its best *G. humifusa*, apparently a choice form of *tinctoria*, very lowly and hairy and richly golden in flower. Nor is a spreading carpet of *G. tinctoria* fl. pl. in full bloom likely to be forgotten by those who possess this ninepenny beauty. There are many more, including *G. sagittalis*, which is, perhaps, the one member of its glorious race I could do without.

Fuchsia procumbens, on the other hand, is the one representative of its tribe which I should part with most regretfully. It is far from being gorgeous and it may not even be pretty; but there is a quaintness about its glistening flowers, with their spots of chocolate and daubs of arsenical green on tubes of honey-coloured wax, which is peculiarly fascinating. This little trailer has, moreover, a cheerful disposition. It is always the

THE BEAUTIFUL TRAILING BROOM, CYTISUS KEWENSIS.

much larger, fiddle-shaped leaves and an accommodating habit of trailing in a semi-scandent manner for several yards in any direction one may desire.

Another little shrub that must not be passed over is *Spiraea decumbens*, sometimes, I believe, sent out as *S. Haequetii*. This might be described as a minute *S. arguta* and is most delightful for any cool, stony bit of ground over and through which it can be permitted to wander at will. The slender, wiry stems of this shrublet rise to about 8 ins., they are furnished with delicate-looking emerald leaves, which are deciduous, and the white flowers, borne in large, loose heads, are remarkably attractive in the mass.

An ideal trailing shrub for a warm place and one which "needs no bush," is the prostrate Rosemary. This is one of those once-grown, always-grown plants, so dear to the happy gardener, and in the same category must be placed the lesser, prostrate *Cotoneasters* and especially *C. humifusa* (Dauмери), which is perhaps more strictly a true trailer than any other. *Cytisus decumbens* is one of the best of its race for the purpose in view, but *C. kewensis* is more elegant by reason of its freer

first of its tardy race to respond to the call of spring, and the fresh, delicate green of its prostrate branches is itself a pleasant thing to meet in the height of summer. *F. procumbens* appears to be quite as robust as any of the *Fuschias* usually considered hardy and does with similar treatment.

The Knotweeds comprise a few trailing species of high merit, *Polygonum Brunonis* (affine) being one of them. This is a Himalayan alpine of much refinement and vigour, making a broad carpet of fresh, evergreen leaves above which it produces a long succession of rose-pink spikes. *P. capitatum* is of much the same habit, but is less pleasing in flower and more prone to shabbiness. Perhaps the best of this class of Knotweed is still *P. vacciniifolium* which, though common enough, will always maintain its position among the choicest of trailing rock plants. It is hardy, a good doer where it has plenty of sun and a cool root-run, and the neat little leaves (said to be evergreen in some districts), which clothe its cushions of wiry stem-assume rich autumn tints.

Coronilla iberica (cappadocica) will make a fine, spreading mass of elegant sea-green foliage which

is surmounted by golden yellow coronets in early summer, and *C. minima* looks as if it were a dwarf form of the same thing. Smaller still, and in some respects even more taking, is our own Hoarshoe Vetch, *Hippocrepis comosa* of the limestone. There is a charm and a daintiness about this little creeper that will attract attention even in mid winter. When, in due season, the fresh, blue-green foliage which drapes the rock face with such a well dressed effect, breaks out into numerous ringlets of rich yellow, one feels a justifiable pride in our native weed. Nor has *H. comosa* any faults. Here, at any rate, it is always well behaved, which cannot be said of some of its kindred, of which the Lotus (*L. corniculatus*) is one. *Lathyrus tuberosus*, another of this numerous clan, can be used with

good effect for sweeping over bold rocks or banks and there are not many species of its kind which can give us clusters of pea-flowers of such large size in so pure and rich a pink. These blossoms are, moreover, sweetly scented and they are freely borne throughout summer and autumn. *L. tuberosus* needs no support when intended for such purposes as the above, for it is perfectly happy in forming a tangled mass firmly knit together with tendrils. This Pea, however, it is well to observe, is liable to become a pest in many soils.

Trailing plants of the very highest order and in the widest choice, I need hardly say will be found among the Alpine Phloxes, Aubrietias and *Helianthemums*. As, however, one of these families alone might occupy several pages, one

must be content to leave it at that. Some allusion must, too, be made to the claims which many of the *Acanthaceae* might put in for notice. Nor can one omit to mention the lovely *Arabis aubrietoides* and the bolder and pinker *A. Sundermannii*, not forgetting *Convolvulus mauritanicus* for trailing over and about any of the above-mentioned, to flower when their season is over. And for use in a similar way what can be more satisfying than the trailing *Oenotheras*; such superb species as *macrocarpa* and *marginata*, with their long, sinuous stems and magnificent goblets of yellow or spotless white being indispensable to any rock garden, not only on account of their intrinsic loveliness, but also because of their late blooming.

NORTH WALES.

ROCK GARDEN CONSTRUCTION—II

ADMITTING that there is still a great deal to be written about the "strategy" as distinct from the "tactics" of rock garden construction, we will in this instalment consider some of the more important points to be borne in mind in the actual laying of the stones. This digression is not made to give variety to the topic; simply because some of the larger questions of general arrangement are governed to great extent by this detail work and can be more intelligibly explained if the detail is discussed first.

Almost all rock gardens are laid out in imitation of stratified outcrops in nature. Such strata were, of course, originally level, but owing to varying causes, natural strata may be found at every conceivable angle. Some strata, indeed, may be found as nearly as possible on end.

FIGURE 5.

If the sole object of a rock garden were to imitate natural phenomena, such an arrangement might perhaps be reproduced. The principal object of a rock garden, however, is to provide a home for

suitable plants. This object can only be achieved if we select very carefully the natural outcrops upon which we model our garden. The "lines" of stratification—so that we may call them so—

FIGURE 6.

must, for instance, be approximately level as they are seen across the outcrop, though a tilt of 10° in either direction is quite feasible and one of 15° may, with care, be arranged.

In order to carry the water to the roots of the plants as well as to ensure the stability of the rock-work, the stones must slope downward and backward from the face into the ground behind. This slope is plainly seen in Fig. 5, which shews a section through a rock garden cliff carrying a path pass-fashion. Take the part above path level and balance it by a similar rocky slope on the right of the path and we have a very typical rock garden arrangement, albeit one which, if undiversified, rapidly becomes monotonous. Here we have two outcrops facing one another, each with the stones dipping backwards—surely an unnatural arrangement! Natural or unnatural, it is a very necessary one; but, fortunately, it does not, when seen, strike most people as unnatural. Fig. 6 suggests the probable reason why.

Fissures, in nature, are frequently caused by bent strata giving way. Very often, in the result, one side or other subsides after the cleavage—causing a "fault"—but that is not always so. This cleavage, on a tiny—oh! how tiny—scale, the opening through which our simple path or tiny trickle of water finds its way, mimics.

If it is decided to tilt appreciably the "strata" as seen at the outcrop, care will have to be taken in the arrangement of the paths and the direction of the tilt, otherwise the work may go on "swimmingly" until, at some corner, "strata" come cheek by jowl which are set at entirely different angles and cannot by any stratagem be reconciled. The point is mentioned here, but the matter is rather an intricate one and will be better dealt with in

detail in another place. Fig. 7 illustrates the disposition of "stratified" rock to form a garden picture. A path, largely formed of stones following the lie of the strata and so arranged as to resemble natural shelves, traverses a wide valley in the rock garden. Between the path and the further cliffs lies a moraine or "pierrier" for choice plants. Those who have visited the Alps will appreciate the difference between the two, though as constructed in English gardens there is little to choose between them as far as external appearances go.

A moraine represents the detritus brought down

FIGURE 7.

by a glacier and is made up, almost entirely, of pieces of stone of various sizes, watered constantly from below. A "pierrier" consists of detritus which accumulates at the foot of a cliff. Though, naturally, varying with the rock of which the cliff is composed, a "pierrier" contains, as a rule, more soil and humus than a true moraine and has not the stream of ice-cold water beneath it. In the rock garden our "stone heap" may be moraine or "pierrier," or even a peat bed (*tourbière*) dressed with stone as best may suit the plants we want to grow or it may be a combination of all three.

The structure of the moraine was detailed a few months ago (April 8, 1922, page 163) and it is not proposed to go into its construction in the present notes. In case, however, a "pierrier" or peat bed is wanted, a few words upon their construction may be apposite. For either, the soil should be taken out to a depth of 2ft. to 2½ft.—the greater depth is the better—and may

be used for banking up the "highlands" of the garden. A "pierrier" may be constructed of about twenty parts of

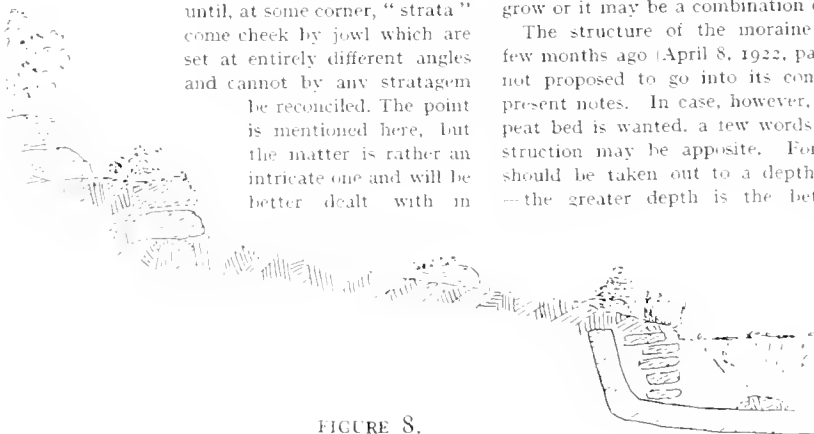

FIGURE 8.

granite chippings mixed with one part each of turfy loam, peat and decayed leaf-soil. If limestone or sandstone is employed a rather larger proportion of stone will be desirable, as such stones disintegrate to some extent in use. The peat bed will consist of fibrous peat and maiden loam—two parts of peat and one part of loam—preferably mixed with fair sized pieces of stone and faced with stone to retain the moisture. As a supply of water underground is very desirable for the peat bed, it may with advantage be made part and parcel of the moraine.

The material for the paths is always a source of controversy in rock garden construction. In so far as these can be constructed of apparently natural ledges of rock the effect is admirable, but it is not feasible to form the whole of the paths in this way. Probably the best material for the remainder is gravel. With most stones an ordinary yellow gravel suits well enough, but if hard paths are wanted through weather-worn limestone rock-work, limestone chips are best.

For many sites and situations greensward is impracticable in the rock garden, but there are places where a rock garden in a green setting is not only possible, but eminently desirable. Fig. 8 shews a section through one side of such a garden which contains at the dip a small sheet of water. This last is, however, by no means a necessary accessory, though water is always a picturesque feature of such a garden. It will be seen that the arrangement of the stone conforms to that in the all-stone garden (Fig. 5), but as a general rule contours in a rock garden on a grass foundation should be far more gentle (and more subtle) than in the older and more ordinary type.

THE BORDER CARNATION

IN some districts Border Carnations may be grown very successfully with but little trouble, in others extra care is needed to accomplish a limited measure of success. The magnificent Perpetual-flowering section has not weaned thousands of amateur cultivators from their love of the Border beauties. Indeed, there are thousands who find, rightly enough, that there is room for both in their gardens.

It is found in some localities that rooted layers do not winter well in the open border and that it is advisable to transfer them direct from the parent plants to a cold frame and, in due course, to plant them in their flowering quarters the following spring. Personally, I have been obliged to follow this plan while living in a South Coast district not far from the borders of Sussex. There was no difficulty with that grand old variety Raby Castle and several others, but in the case of many of the newer sorts it was quite different.

The heavier soils need very careful treatment. The planting may be done about the middle of March in bad weather; a little earlier in good. End of February planting is practicable, even desirable, where the soil is light.

In no case should the cultivator tread upon the border after planting. Where organic manures are needed, well rotted dung should be used, buried so as to be just below the roots when the Carnations are planted. It is not conducive to healthy growth to mix the manure with the surface soil and so bring it into direct contact with the roots at that stage. When the plants have become established and their roots begin to permeate the soil, the resultant growth will be much benefited through the presence of suitable manure within reach. Those who have not given this plan a trial should do so this spring. G. G.

SOME EARLY-FLOWERING PLANTS

ALTHOUGH severe winters are, fortunately, uncommon in this district (West Porlock, Somerset), it is seldom that January passes with but two nights on which the thermometer dropped to below freezing point, as has been the case this year. Heavy rain and a few hailstorms occurred during

variety has flowered at least as freely as it did last season. *Iris histrioides* opened its first bud on January 4, and a small patch was the glory of the rock garden for over a fortnight. *I. reticulata* followed on at the end of the month; there is something quite amazing about the rapidity with which its buds develop and burst into bloom.

THE CHARMING EARLY-FLOWERING SAXIFRAGA ELIZABETHÆ.

the first week of the New Year, and there was very little sunshine throughout the month; but in spite of the mildness of the winter, plant life on the whole is not unduly forward. It is interesting to compare the effect of the wet, dull summer of 1922 on various plants with that of the dry, baking season of 1921. In some instances the results are only what one would have expected, but in other cases they are surprising. In the case of the two Winter Honeysuckles, for instance, *Lonicera Standishii* has been a sheet of bloom since Christmas, but *L. fragrantissima* has grudgingly produced only a few flowers half hidden among its evergreen leaves. Perhaps it is as well that nurserymen so frequently send out *L. Standishii* under the name of *fragrantissima*! It is certainly a much more satisfactory shrub, though the individual flowers of *L. fragrantissima* are slightly larger and gain by having the association of the young foliage. They are both deliciously scented, most especially so in the evening, like the early *Daphnes* which cater for night-flying moths.

As usual, the Winter Aconites in the grass under an Apple tree were in flower on New Year's Day, and this year won their annual race with *Crocus Imperati* and the first of the Snowdrops. Whenever there was a gleam of sunshine *Crocus Imperati* and *C. Sieberi* opened out wide in response, but in dull weather when no fertilising bees were on the wing they wisely remained closed and thus protected their pollen. *Iris unguicularis* has plainly shewn its disapproval of last summer's sunless days—as, indeed, one knew it would. Clumps which bore over 1,500 flowers last winter only produced 400 by the end of January this year. It is worth noting, however, that the white

Slugs seem to have a special passion for defiling the flowers and gnaw them through halfway up the stem. Another cheerful bit of colour was provided by a small clump of *Cyclamen Coum* nestling in the shelter of the slender leafless twigs of *Corylopsis pauciflora* from which the pale lemon cowslip-like flowers already dangled. The gayest shrubs in the garden were the bushes of *Cytisus racemosus*, 6ft. high and as much in diameter, literally smothered from top to bottom with the delicious golden racemes. Seldom are they able to flower quite so lavishly in the open in mid-winter, though they are scarcely ever entirely out of bloom at any season. Where it will succeed outdoors this favourite greenhouse plant develops a beauty never realised when confined to a pot. *Coronilla valentina* is useful also for winter flowering, and never fails to produce masses of its rather shrill yellow flowers, strongly scented, too, but in no way comparable to the *Cytisus*. Though the *Coronilla* is probably harder than the *Cytisus*, it does not seem to be a long-lived shrub, but as it obligingly sows itself and grows very rapidly, the loss of an old plant can easily be remedied.

The Winter-Sweet, *Chimonanthus fragrans*, seems to have been flowering well in most gardens this winter, which is rather surprising when one thought it required a thorough ripening of the wood. Is it possible that some of the stored-up energy from the heat of 1921 is finding expression this winter? On the other hand, both the winter-flowering Clematises (*C. calycina* and *C. cirrhosa*), which were covered with bloom last year, have hardly flowered at all this winter. It is strange also to see *Cianthus puniceus albus* with flower-buds hanging from every shoot in the greatest

profusion, a few precocious flowers being open early in the New Year. Needless to say, the dwarf Heaths (*Erica carnea* and *E. darleyensis*) greatly preferred the cool of the past summer to the scorching of the previous one; both were in flower at the beginning of the month and will continue in beauty for many weeks. *Erica Veitchii* is one of the most valuable shrubs for winter flowering that has ever been raised. From the middle of January the buds begin to open till the entire plant is wreathed in tiny white bells, sweet with the real heather scent. It does not take the bees long to find their way to a bush of *E. Veitchii* in bloom! *Grevillea rosmarinifolia* is another satisfactory shrub which rarely fails to give a good account of itself; its quaint-shaped pink flowers shew up well against the warm dark green foliage.

Visitors from cold districts are always surprised to see the vigour with which the *Acacias* (*Mimosa*) flourish in the open in the south-west. They dislike exposure to bitter winds far more than severe frosts, but in a reasonably sheltered situation they go ahead very rapidly. A seedling *Acacia falcata* only three years old is now about 8ft. high in spite of having had its main shoot broken by snow last April. It began to flower early in January, but this species appears to take several years as a rule before it flowers really profusely. Fortunately, the absence of frost encouraged *Lithospermum rosmarinifolium* to bedeck itself with a rich crop of glorious blue flowers. It began to flower in November, and apparently means to carry on till the spring.

Daffodils were represented in January by the ever-welcome Hoop Petticoat varieties, and these were accompanied in the last few days of the month by *Narcissus minimus*, a most perfect little flower. The Scilly White Polyanthus *Narcissi* missed their usual summer's baking, and consequently came up very late and with poor promise of bloom. They grow alongside the clumps of *Iris unguicularis* under a warm wall, and have hitherto revelled in the position. Golden Spur Daffodils were shewing colour in the open border by the end of January, and most other varieties were coming on rapidly. The Riviera variety of that pestilential weed, the Lesser Celandine, is quite a good plant which does not wander unduly, and opened the first of its very large golden flowers in January. Though very distinct for gardening purposes, it is probably only a large variety of our tannish *Ranunculus Ficaria*.

Saxifraga Elizabethae was the first of its race to greet the New Year, but by the end of the month it was joined by the crimson-purple *S. oppositifolia*, one of the best of British natives grown in rock gardens. It is an extremely variable plant, as one might expect from its very extensive range, which includes the High Alps and sea-level at Spitzbergen. Some forms seem much more amenable to cultivation than others. The first flowers of the handsome *S. Megasea ligulata* conceal themselves among the large leathery leaves, but before January had passed others were peeping out well above the sheltering foliage. That cheerful little annual *Diopsidium acaule* has flowered without ceasing all winter and brightens up the soil in front of a colony of the stately green-flowered Corsican Hellebore. The rosy-hued *Helleborus olympicus* and the white-purple-spotted *H. zuttatus* rushed into full bloom by the third week of January, before the true Christmas Roses were over. Divided plants of these Hellebores always take some time to re-establish themselves, but seedlings are very easily raised (self-sown plants often appear), and in two or three years make fine healthy tree-flowering plants. Moreover, there is always the chance

of some good variation occurring among the seedlings. Some of the larger Spurges look well planted among Hellebores, whose poisonous properties they also possess. A beautiful glaucous species, which is probably *Euphorbia Characias*, flowered throughout the month, and its tall stems of quaintly formed green and brown flowers were very decorative. All these evergreen Spurges are far too seldom seen outside botanic gardens, for though not showy, they all possess considerable beauty of form.

There were not many berries left in the garden by the New Year, but *Pyracantha angustifolia* remained one of the gayest features of the month with its branches wreathed in masses of orange berries. The large branching inflorescence of *Cordyline australis* also was full of interest, with its profuse crop of tiny white berries containing the glossy black seeds. As birds had begun to take them, the inflorescence was cut and the berries saved for sowing.

West Porlock.

N. G. HADDEN

A BIG SHOW AT WESTMINSTER

THERE was a great increase as regards bulk in the exhibits at the R.H.S. Hall, Vincent Square, on February 13 last and a quite corresponding increase in the attendance. During the early part of the afternoon the attendance was so great that difficulty was experienced in viewing the exhibits. While there were more flowers than might have been expected at a mid-February meeting, it must be confessed that there was a deal of repetition and not all exhibits were of first-class quality. That the Floral Committee shared this opinion was evident from the comparatively few awards they recommended. The greatest increase was in alpinines and it is a moot point whether or not it is wise to force these little plants into premature flowering as is so often done nowadays.

The outstanding floral exhibit was the magnificent collection of greenhouse *Cyclamens* arranged by Messrs. Sutton and Sons, and it is no exaggeration

to say that it was the finest display of these plants seen at the R.H.S. meetings. We should not like to say definitely how many plants this monster collection contained, but the quality was so high that there was not one second-rate plant among the several hundreds. The massed plants of such as the glowing Salmon Scarlet, the giant Silver-leaved Salmon, the deep crimson Vulcan and Giant White, to name only a few of the many distinct varieties, made a memorable display, while the crested flowers of Mrs. Buckston intrigued many visitors. On a table space near, by Messrs. Sutton and Sons set out a smaller exhibit of *Primula sinensis* and *stellata* varieties and these shewed again similar high-class strains and expert cultivation. The R.H.S. gold medal has never been more worthily awarded than on the present occasion.

A meritorious collection of greenhouse *Cyclamens* was sent from the gardens of Mr. E. Wormald, Sheepwell House, Potters Bar, and at any other time these would have excited even greater envy and admiration than they received.

Azaleas, both the evergreen indica and the deciduous varieties were shewn as excellent plants by various exhibitors, but it was the warm, glowing colours of the mollis-sinensis varieties shewn by Messrs. R. and G. Cuthbert that excited most attention. Among their Azaleas Messrs. L. R. Russell, Limited, had numerous forced hardy shrubs, particularly *Prunus triloba*. Other useful forced shrubs at the show were the many plants of the fragrant *Viburnum Carlesii*, in a collection from Messrs. Wallace and Co., who also had well flowered examples of *Prunus triloba* and again shewed pans of interesting and beautiful *Crocus* species.

A goodly bush of the slow-growing but long-flowering *Andromeda floribunda* was noted in an exhibit by Messrs. J. Cneal and Sons. The first flowers on the erect panicles of this American shrub will often be open at Christmas and it will be the end of March before

VIVID ORANGE AND SCARLET TRUSSES OF THE GREENHOUSE RHODODENDRON NE PLUS ULTRA.

THE SOFT MAUVE PRIMULA CALCIPHILA.

the last have discoloured and fallen. The flowers last well and will open in a cut state. Bright shrub colour was to be seen in the berries of the dwarf plants of *Skimmia japonica* shown by Mr. G. G. Whitelegg, who also had some beautiful silvery rosettes of *Saxifraga longifolia*.

Lady Aberconway sent from her North Wales garden trusses of early *Rhododendrons*. In the centre there was a stand of *R. Nobleanum* showing interesting variation from the type. Silberhad's Early Pink is somewhat like a smaller, more waved *Gloria Mundi*, while the larger trusses of *R. sutchinense* were a delicately beautiful pale pink.

As flowering plants the best alpiners were the pots and pans staged by Mr. Mark Fenwick. There were a great many pans of *Saxifraga Burseriana* and several admirably flowered ones of the dainty pink *S. Irvingii*. In the annex Messrs. R. Tucker and Sons had a great variety of alpiners in small pots. *Primula juliae* bore flowers of intense colouring. Blue Primroses of great merit were shown by Messrs. Blackmore and Langdon. *Soldanella alpina* was included by Messrs. Maxwell and Beale in their collection, which also contained some plants in flower of the *Mesembryanthemum turbinatum* roseum and album, which one sees growing so luxuriantly in such places as the seashores of Cornwall and the Isle of Wight. The dainty little *Bellis sylvestris* was included in several collections of alpiners, and the crimson flowers made bright patches of colour.

The Narcissus Committee met for the first time this year but did not have any novelty of merit before it. Messrs. R. H. Bath, Limited, exhibited a very creditable collection of Tulips and Daffodils growing in bowls of fibre. As a background to their alpiners Messrs. Barr and Sons arranged some very good pots of Narcissi and Hyacinths and Messrs. Carter and Co., Limited, had one of their artistic displays of similar bulbs, with Primulas.

A large exhibit of Citruses, growing on bushes in pots and as gathered fruits, was somewhat an unusual feature and these were brought by Messrs. T. Rivers and Son. The bush of Citron of Paradise, which bore twenty large fruits, was said to be the best ever seen at a show.

A small but particularly good collection of Potato tubers was made by Messrs. Dobbie,

and in this the purple eyes of Katie Glover and Di Vernon seemed to fascinate many visitors.

NEW AND RARE PLANTS.

Primula calciphila.—This is a daintily beautiful greenhouse plant from the cliffs of Ichang, West China. In general appearance it is a flattish, very free-flowering species of *P. stellata* type, with smallish, pale green leaves somewhat similar to those of the old double white *Primula*. The fact, however, that it consistently refuses to hybridise with any of the *Primula sinensis* types, although when selfed it seeds freely, disposes of the suggestion that this is the true *Primula sinensis*. The flowers are stellate with well rounded petals and rather more than an inch across. They are of delicate pale mauve in colour and have a small pale lemon

eye. Award of merit to the Director, Royal Botanic Gardens, Kew.

Prunus Conradinæ.—In general characteristics the flowering branches of this small tree suggest a more graceful and larger flowered *Prunus Bissardi*, but it is one of Wilson's introductions from Western China. Like the *P. cerasifera* varieties the young leaves of this tree are purplish and become reddish-purple in the autumn. The specimen now flowering in the *Prunus* collection at Kew is very beautiful with the graceful branches wreathed with the palest blush flowers. So far as is known the tree has not fruited in cultivation. Award of merit to the Director, Royal Botanic Gardens, Kew.

Rhododendron Ne Plus Ultra.—The magnificent plant of this hybrid greenhouse *Rhododendron* was decidedly the feature of the Show and we doubt whether finer trusses of this type have ever before been seen at any exhibition. On the entry card it was stated to be a cross between *R. javanicum* and *R. jasminiflorum*, but its appearance gives no suggestion of the latter parentage, and in his book on "Rhododendrons and Azaleas," "Present Day Gardening Series," W. Watson, writing with an authoritative knowledge of his subject, states that *R. Ne Plus Ultra* is a cross between *R. javanicum* and *R. Duchess of Edinburgh*, the latter being a hybrid between *R. Lobbii* and *R. Brookeanum*. The vivid, glowing, rich orange-scarlet flowers, seemed to vibrate with glorious colour. First-class certificate to Lieutenant-Colonel Sir George Holford.

Dendrobium Gatton Monarch var. F. J. Hanbury.—This beautiful Dendrobe may be termed a glorified *D. nobile*, which has a definite white band around its rich, velvety, purple throat. First-class certificate to Mr. F. J. Hanbury.

Odontioda Baroness Schroder.—A magnificent variety bearing large perfectly formed crimson-claret flowers, lightly edged with white. The lip is elegantly waved, well margined with white and lightly spangled with gold on the crest. First-class certificate to Messrs. Charlesworth and Co.

Odontoglossum Purple Queen.—This is a very uncommon flower. The general colour impression is blue-violet tinting on a brownish ground and the flowers have narrow white edges, while the base of the lip is wholly white. Award of merit to Mr. J. J. Bolton.

AN ADMIRABLE BLUSH-COLOURED ORNAMENTAL PLUM, PRUNUS CONRADINÆ.

WINTER-FLOWERING BEGONIAS

The Gloire de Lorraine Group.

SOME years ago *Gloire de Lorraine* was the winter-flowering Begonia; to-day it is only a type—one of many—and it is quite possible to have as rich and varied a display of colour during winter as the tuberous varieties provide in summer. Nor are we confined to singles; superb double flowers in scarlet, crimson, salmon, rose, orange, apricot, etc., are all plentiful. Many of these produce individual flowers zins. to zins. across, but always with the Lorraine habit, building themselves up into perfect pyramids of loveliness that must be seen to be appreciated or even imagined.

This brings us to a consideration of the methods of propagation and the cultural treatment of the plants so obtained. After flowering, a period of rest is imperative and to this end the plants should be cut back somewhat and kept only just moist at the roots. Take care that they are kept in a good light in a temperature between 60° and 70° and a large number of short, sturdy little basal shoots will soon begin to develop. These should be in the best possible condition for our purpose early in April and, from then onwards right up to August, a succession of cuttings will be obtainable that will give a continuity of flowering plants right through winter and early spring.

The early-rooted cuttings will, naturally, give the strongest, finest and largest plants, those struck later, however, being especially useful for smaller specimens. Such are very suitable for indoor decoration. Never attempt to keep them within doors too long, however, or this will result in the buds dropping and the early ruination of the plants. Having prepared your plants and obtained a good supply of short-jointed, stocky shoots about zins. in length, these should be taken off from the base of the plants, severing each with a very sharp knife just beneath a joint. The tissue is very succulent and the sharp knife is very important or the stem is readily bruised and then decay sets in. Crock the pots or pans carefully in which the cuttings are to be inserted so that there is no question as to efficient drainage, and cover the crocks with a layer of moss before any soil is put in; this prevents the finer particles of earth from washing down into the drainage and choking it when watering. A fine soil is best, one composed of two parts sifted loam to one each of leaf-mould and silver sand being excellent. Mix this well and allow half a dozen cuttings to each 5-inch pot. The lower leaves should be removed and the soil made quite firm round each, each pot being afterwards lightly watered and plunged in a propagating frame with gentle bottom heat. Keep rather close for a time, taking care to water moderately and constantly remove all leaves that show signs of decay. As roots form, a little air should be given and, as they become accustomed to this, the pots should be withdrawn from the propagator and stood in a cooler temperature of 55° to 65°. Dew them constantly overhead and shade from bright sunshine.

These winter-flowering Begonias are specially addicted to premature flowering and the only way to avoid this is by selecting strong basal shoots from which to form the cuttings, and to grow them in a moist atmosphere so as to promote steady and continuous growth. Dew them overhead through a fine rose with tepid water several times a day and, as soon as strong enough, pot off singly. For this potting, the soil need not be so fine, while a considerable reduction in the quantity of sand

may be made. Let the soil be fairly firm, but not hard, maintain a temperature of 55° to 60° at night, with a rise of 5° to 10° by day, and continue light shading and syringing as before. Never allow the young plants to stand still and, directly the first pots are filled with roots, transfer them to a larger size and repeat this as they become filled with roots.

For the second and all subsequent pottings, the following compost should be employed. Fibrous loam two parts, peat one part, with half a part each of coarse silver sand, leaf-mould and dry cow manure, with a generous dusting of bonfire ashes. Turn these together again and again, so that everything is really well mixed and, after potting, place a neat green stake at the centre of each pot so that the growths can be lightly looped up to this as they

advance. If the plants fail to branch freely enough stop the points once or twice so as to encourage side growths and, as these in turn become long enough, loop them up to the central support. Do not shade too heavily during summer; this is only necessary when the sun is bright and the more light the plants receive the shorter and sturdier the growth will be. Air must be admitted freely, though anything like draught should be strictly avoided. Watch the atmosphere; this must never become too dry, and keep the temperature steady at 55° by night rising to about 65° by day.

Once the flowering pots are well filled with roots and buds are commencing to form, do not omit to feed regularly and generously with weak liquid manures; this makes all the difference to both size and depth of colouring in the blooms. **TROPICA.**

NOTES OF THE WEEK

NEXT week's issue of *THE GARDEN* will be a special Spring Planting Number, which it is hoped will prove of more than usual interest. Bulbs for spring planting—Lilies and Gladioli—will receive special attention; but shrubs and herbaceous plants will also come under review.

The Royal Horticultural Society.—The Annual General Meeting of the Royal Horticultural Society has come and gone. As expected, the criticisms

of the condition of the Wisley Gardens and of the Council's policy as regards Wisley have borne fruit. An improvement is promised, and Fellows must possess their souls in patience awhile and hope that expectations will be realised. Is it too much to hope that the Council will reconsider its attitude with regard to the Wisley trials? We are perfectly aware that they have made no promise in this direction, but now that Wisley is under discussion it would be a good opportunity to do

so. It is very easy for the management of a big society such as this to get out of touch with the feeling of the rank and file, whose opportunity for expounding their views at the annual meeting is small. Not all Fellows, we imagine, are in the habit of addressing public meetings, and Lord Lambourne is perhaps too capable a Chairman in this respect, for, if courteous, he is certainly not helpful to those who wish to lay their views before him and the meeting. The financial results for the past year, as disclosed in the Annual Report, are certainly excellent, and everyone concerned, from the President and Treasurer downwards is to be congratulated upon the extraordinarily strong financial position of the Society.

The Hardest African Lily.—

The picture shews a clump of *Agapanthus umbellatus* var. *Mooreanus* at Gravetye. This plant is largely cultivated there and is exceedingly effective when massed, though a black and white picture of the plant growing in quantity is not an interesting one. The plant is very much hardier than the type species; indeed, it would probably prove hardy in almost every district and is very distinct in every way. The blossoms are similar in colour, but the flower stems are more slender and graceful and the foliage is much shorter and less imposing. This, naturally, detracts from it as a foliage plant, but it gives added character and dignity to the flowers. Unlike the type plant, the variety *Mooreanus* is deciduous. This is a good time to transplant it.

AGAPANTHUS MOOREANUS, HARDEST OF "AFRICAN LILIES," AT GRAVETYE.

CORRESPONDENCE

OUTDOOR WINTER GARDENS.

AS the winter is longer than the summer, so, in some respects, is the winter garden more important than the summer garden. One does so enjoy flowers at this time of the year and it will probably be two months before the spring garden will be enjoyable. I certainly get great pleasure sitting in my winter garden, which, after all, is only about 35ft. square, so that there is nothing very costly in cultivating such a little piece of ground. There are so many plants which flower in the winter that there is no trouble in furnishing a winter garden. I counted over thirty different kinds of flowers on February 4. On the walls *Cornus mascula*, *Garrya elliptica*, Winter Jasmine and *Laurustinus* are all in full bloom. Then there are two beds of *Rhododendron præcox*, with *Erica carnea* below. Other beds have Lent Lilies, Blue-eyed Mary and *Violas*, yellow, white and lavender *Crocuses*, *Snowdrops* and lots of *Iris reticulata* in two colours to help to make the garden bright; but what troubles me is why do people so seldom indulge in a winter garden.—THACKERAY TURNER, *Westbrook, Godalming*.

IRIS RETICULATA.

TWELVE bulbs of *Iris reticulata* planted in fibre in a bowl in November and grown in a cold greenhouse are now coming into flower. Another bulb in the open border left from last year is in full flower to-day (Feb. 9) and rather taller than those in the house.—L. D., *Wells, Somerset*.

SOME EARLY SPRING FLOWERS.

ON page 60 in THE GARDEN of February 3 I notice that Mr. Chapman mentions having *Iris reticulata* in bloom under glass on January 16. My first blooms out of doors opened on January 24, and the plants were soon in full bloom. *Narcissus minimus* was out on January 29. It is on a rather dry little mound at the base of an Oak tree. *Narcissus cyclamineus* opened on January 31. Both varieties were also in bloom in a cool house, but only a few days ahead of the outdoor bulbs. The mild weather accounts for this, I suppose. I do not know when these two varieties are supposed to bloom. The extraordinary warmth and bright sun on February 3, 4 and 5 has brought everything on far too quickly, but they have had a check. Here *Prunus Mume* is opening its first flowers, *Prunus Pissardi* breaking into flower and foliage, *Leptospermum Boscaweni* in bloom and many other shrubs are all shewing buds far too forward. I only hope they will be kept back until they can break and bloom safely.—G. H. DALRYMPLE, *Bartley, Hants*.

PRIMULA WINTERI OUTDOORS.

HAVING read with much interest the note on *Primula Winteri* in the issue of THE GARDEN of February 10, I think that some of your readers might like to know that I have grown it out of doors for the last nine or ten years here, and have now some thirteen plants either in bloom or with buds just opening. I find they are very hardy as regards cold, and passed unhurt through the terrible spring of 1917, when the mercury fell to 4° on March 9. Also they seem to enjoy a moist root-run at all seasons and as much rain as they can get between May and October. Indeed the plants suffered much from the dry summers of 1919 and 1921 and had fewer blooms in the following springs. But from the time the white winter leaves begin to shew—generally about October 1—they must be kept as dry as possible overhead,

and I have tried to solve this problem by planting them with a large stone at their backs, so to speak, against which I place convex pieces of glass (I find broken cloches or crystal fruit dishes the

SOFT LAVENDER BLOSSOMS OF PRIMULA WINTERI.

most useful). This may somewhat disfigure the rock garden; but, after all, it is easy to remove the glasses on fine dry days or when one expects a visitor to be taken round the rock garden! My plants are mostly on a northern slope with high *Rhododendrons* behind them, so they get very little sunshine but seem to thrive without it.—H. M. B., *Berwickshire*.

EARLY GROWTH.

I THOUGHT you would be interested to hear of the following plants, etc., which are a fortnight to a month early even for this garden, on the borders of Devon and Somerset: Three varieties of *Eremuri*, and *Lilium Henryi*, *testaceum*, *tigrinum* F. *giganteum* are 3ins. to 4ins. above ground. Crown Imperials, *Ribes*, *Solanum crispum* and many *Daffodils* are in bud or just out, together with, of course, *Prunus Pissardi*; also scarlet *Anemone* and the other ordinary sorts, and *Rhododendron præcox*. My newly planted Chinese shrubs, such as *Staphylea colehica* and *Halesia tetraptera* have burst their buds! One wonders if they will ever survive the late frosts as they will be so far on.—F. L. P. BAKER, *Creekerne, Somerset*.

STRAWBERRIES AND ASPARAGUS.

MR. ENGLEHEART (page 47) is a difficult man to convince that his own views and opinions are not the best—he is satisfied that they are and nothing further, therefore, remains to be said or written. My personal experience reaches the half century and I hold staunchly to what I wrote, the substance of which was that runners of equal excellence and earliness can be secured from one year old fruiting plants as from maidens. Mr. Engleheart would, perhaps, differentiate between one year old plants and maidens, but there is no difference in age—the essential difference is that

my runners shall come from one year old plants which have fruited and his from one year old plants which have not fruited. Runners from the last named will run a little bigger, but they will not give superior results. I, too, will ask readers to try both systems and report results. If Mr. Engleheart used turves he would not find the necessity to

move the plants to hard ground; they would remain *in situ* until the actual moment for planting. The sound objection to small pots lies in the fact that, under forced delay in planting out, the roots mat hard round the porous sides and do not take immediately to the new soil as they do when moved at the crucial moment or from turves, since there is no matting in the latter case. I did not doubt the ease or the necessity of lifting *Daffodil* bulbs, but simply stated that it was no more "natural" than lifting *Asparagus* roots and obviously that is a fact since Nature would lift only by earthquakes—by lifting and planting we improve upon Nature. It is a fallacy to suppose that *Asparagus* is difficult to move. It presents no more difficulties in the process than most other plants, provided that its fleshy roots are not allowed to become dry and shrivelled by exposure to the air. Unless there is imperative need for haste I always advise sowing for *Asparagus* and my sole reason is that it is cheaper.—W. H. LODGE,

PLANTS FOR ABROAD.

YOU recently printed a letter from M. Corveon about the difficulty of importing plants from England, and the same difficulty exists in Italy, due to a misapprehension on the part of the British P.O. authorities. They ask for an Italian permit for importation before posting plants, and the Italian Ministry of Agriculture will not give this permit because it is not required! I have twice had *Roses* from Mr. Easlea and *Carnations* from Mr. Douglas by parcel post with no trouble (perhaps their post offices were in blessed ignorance of this ruling), but Messrs. Allwood could send me nothing because their local P.O. would not allow the parcel to leave without the Italian permit. It would seem in the interest of British growers to clear up this difficulty with their General P.O., and I hope your paper can help.—A ROMAN SUBSCRIBER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Celery.—If an early autumn supply is needed, a small sowing of a white variety should be made at once. Sow the seeds thinly in pans of light soil, place them in a warm, moist house, and when germination is apparent keep the young plants near the roof glass to prevent them being drawn. When the seedlings are large enough, prick them off in boxes of good soil, and when they are well established gradually harden them off.

Turnips.—On a warm border a few lines of Turnip seed may be sown, selecting a white variety, such as Snowball. The drills should be 1 ft. apart, and the thinning of the seedlings ought to be done as early as possible. This is just a chance crop, larger sowings being made a few weeks later.

Cauliflowers.—Early Cauliflowers are often in demand, so it will be advisable to make a small sowing of First Crop or Magnum Bonum directly the ground is suitable. Sow the seeds thinly and transfer the young plants to their permanent quarters when they have made three or four leaves. Cauliflowers enjoy a generous soil, and it should be well dug and liberally manured a few weeks before it is needed. Protect the seed-beds from birds if necessary. An occasional sprinkling of soot will hold slugs in check until the plants become too large for these marauders.

Globe Artichokes.—If these plants have been protected with leaves or straw litter, the material should now be removed or dug in between the rows. New beds can be made from side shoots or suckers, planting them in lines 5 ft. apart and half that distance between the plants.

The Flower Garden.

Delphiniums.—These delightful perennial plants are readily raised from seeds, and I can recommend this method of propagation. A large percentage of seedlings will produce flowers quite up to or above the average. Seeds should now be sown in the open ground in drills 1 ft. apart, just covering the seeds with fine soil. Slugs are often the cause of failure with these plants, so it is advisable to give the seed-bed a generous sprinkling of soot. When the young plants are large enough, transfer to an open piece of ground where it is intended for them to bloom. Named varieties may be increased by cuttings directly the new shoots are large enough for removal from the parent plant. They will form roots if placed in a cold frame. A number of "annual" varieties are in commerce, and they ought to be borne in mind, because they bloom freely towards the end of summer.

Fruit Under Glass.

Figs are often grown under glass, and the trees can be planted out in a border or grown in pots or tubs, the latter method being often adopted, as the Fig thrives best in a somewhat restricted root-run. The growths of trees planted out should be trained over the trellis, which ought to be about 2 ft. from the roof glass, and in tying in the shoots, overcrowding must be avoided. Figs will bear at least two crops during the year, the most important being the one that is produced on the current year's growth. Pot trees may be placed outside until there is space in the orchard-house, and any trees brought in during March or April will produce a later crop. The repotting should have been done, so when growth is well started the roots may be fed with liquid manure, and after being brought inside they must not suffer from the lack of moisture at the base. Seldom is a house devoted solely to Figs, but success can be attained by growing them with other fruits and affording them similar treatment. When the new growths are 5 ins. or 6 ins. in length, pinch out the centres to assist in the formation of fruits.

The Hardy Fruit Garden.

Protection of Blossom. Some material should be in readiness for protecting the bloom of such trees as Peaches, Nectarines and Apricots on frosty nights. Light shading material or canvas is excellent, but care must be taken to prevent it flapping against the flowers during the night, and if poles are placed at intervals in front of the trees less injury is likely to accrue. Fish netting of double thickness can also be recommended, but whatever is employed it ought to be removed directly the temperature rises above freezing point.

T. W. BRISCOE

(Gardener to W. R. Lyaght, Esq.),
Castleford, Cheshire, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Shallots are very useful, especially in gardens which are much troubled with the onion fly. They should be planted as soon as the state of the ground will permit. The ground having been dug, or torked over, it should be raked smooth, the line should then be stretched and the Shallots planted along the line 4 ins. apart, the bulbs being pressed into the soil half their depth. A foot should be allowed between the lines.

Horseradish.—If not already attended to, a fresh plantation should be made. Well enriched and deeply wrought soil is necessary for the production of strong thongs. Plant pieces 1 ft. apart and 1 ft. between the lines.

Lettuces.—Where an early sowing was made in gentle heat, the seedlings should be pricked off into boxes of moderately rich soil as soon as they are large enough to handle. Prick out at about 4 ins. apart as they should be allowed fully to develop in the boxes.

Sea Kale.—Lift the remainder of the crop and select the strongest crowns for forcing. Sufficient secondary crowns should then be planted when weather permits for next season's supply. Plant in rows 2 ft. apart, allowing 18 ins. between the plants in the row. Sea Kale requires a rich soil with a little salt in it.

Mustard and Cress.—It will still be necessary to make weekly sowings indoors as the plants do little good in the open before April and in any case are always more tender and succulent when grown quickly in a little heat.

The Hardy Fruit Garden.

Strawberries.—Dig between the lines of old plantations and then apply a top-dressing of half-decayed farmyard manure. The latter supplies nutriment to the plants and conserves moisture during the summer.

Fruit Under Glass.

Vines.—Both in the early and later houses the temperature should be gradually raised, 1° a week being sufficient. Attend carefully to ventilation, avoiding cold draughts however. Utilise solar heat as far as possible. Damp the pathways in the morning, and in the afternoon when shutting up the houses. It is a mistake to use the syringe too freely, especially during wet or dull weather. If air roots appear it is a sure sign that too much moisture is being applied.

The Orchard House.—As the more precocious trees come into flower they should be assisted in the matter of pollination by being sharply tapped sometime during the forenoon. Damp the pathways twice a day in bright clear weather, but in dull or wet weather the afternoon damping will be sufficient; the aim should be to maintain a buoyant atmosphere without admitting cold draughts.

Late Tomatoes.—A sowing should now be made for cultivation in frames or other cool structures. In order to ensure vigorous plants from the start the seeds should be sown singly, at a distance of about an inch apart. A temperature ranging from 55° to 60° will be suitable for them.

The Flower Garden.

Early Chrysanthemums.—Cuttings of these will now be plentiful, so sufficient should be taken and inserted for next season's display. There are two methods of preparing the stock, the first is to insert the cuttings rather thickly in pots, 5 ins. pots being a suitable size. When rooted the cuttings are potted off singly in 3-in. pots and are gradually hardened off preparatory to planting. The second method, which entails less labour and produces quite satisfactory results, is as follows. Prepare a sufficient number of propagating boxes by placing a good layer of fibrous loam in the bottom and filling them up firmly with a rather sandy compost. Then, having prepared the cuttings, insert them at 2 ins. or 2½ ins. apart, and when rooted harden them off gradually and plant out direct from the boxes.

Geraniums. The hey-day of their popularity is past, but Paul Crampel and even Henry Jacoby still have their admirers. They should now be potted from the propagating boxes into 3½ in. pots and accommodated in ainery that has been started.

CLAS. COMFORT.

Formerly Head-gardener to Mrs. Haig, Broomfield, Davidson's Mans, Middlethian.

GREENHOUSE AND CONSERVATORY.

Luculia gratissima is a beautiful plant for the greenhouse or conservatory, especially if it can be planted out in a well drained hed or border. In fact, this plant is never long happy under pot cultivation. It produces its large trusses of fragrant pink flowers during the autumn and winter months. During February it should be pruned back hard and kept rather dry at the root until it breaks into fresh growth, which it will soon do if the plants are sprayed several times each day during bright weather. This plant is very subject to attacks of begonia mite, which, however, can be prevented by the use of a sulphur vaporiser. This has always, and not without reason, been considered a difficult plant to propagate. Cuttings should be made from the young growth when it is some 3 ins. to 4 ins. in length, and will root either from nodal or internodal cuttings. They should be inserted singly in thumb pots in light sandy soil, plunging the pots in a close propagating case with slight bottom heat at command. One of the chief factors of success is never to allow the cuttings to flag. *L. pinciana*, the only other species, has white flowers, but it is not so generally cultivated as *L. gratissima*.

Daphne odora (more generally known as *D. indica*), on account of its delicious fragrance is always a great favourite, but is by no means an easy plant to cultivate successfully, especially in pots, and is generally seen at its best when planted out in a well drained border in the conservatory. The trade growers usually graft this plant on stocks of a stronger-growing species. The plant, however, is quite easily propagated by means of cuttings taken from healthy plants, using medium-sized shoots about 3 ins. in length. They are best inserted singly in small pots in a compost of sandy loam and peat, plunging the pots in a close case with slight bottom heat. This plant requires free drainage and careful watering at all times.

Maurandias.—There are several species of *Maurandias* which are very useful as climbing plants for furnishing wires and rafters in the greenhouse during the summer months. They are all easily raised from seed sown at this time, and as they will flower the same season it is just as well to treat them as annuals. Their cultivation presents no difficulty as they grow quite well in any ordinary potting compost, and they may be grown in pots or planted out in beds or borders in the conservatory. The principal species are *M. atrosanguinea*, *M. Barclayana*, *M. crubescens*, *M. scandens* (syn. *Lophospermum scandens*) and *M. semperflorens*. *M. Purpurea* has a perennial root stock which may be stored dry during the winter. This species is not a climber like the others, but makes slender shoots about 2 ft. in length, which require to be supported by neat stakes.

Ipomœa rubro-cœrulea is another annual climber which should be more generally grown for the summer decoration of the greenhouse, as its wonderful blue flowers attract much attention. It is easily raised from seed sown at this time and again later on in the season to give a succession of plants. This plant requires rather careful cultivation, care in watering being essential; it is also subject to attacks of red spider, which should be prevented or kept in check by the use of the syringe. The plants should flower well in 6 in. pots and may be neatly trained round supports or allowed to run up strings or wires under the roof glass. They will also do well if they can be planted out in well drained beds or borders where they can get plenty of light. In the south this plant sometimes thrives when planted outdoors in warm, light soil against a south wall.

BEAUTIFUL VELVETY LAWNS

That is how they are often described in novels, but how seldom do they come up to the ideal? Instead of being "velvety" they are often brown or patchy and full of weeds. What is the remedy for poor lawns? Many things contribute, such as mowing, rolling and weeding, but the most important point is to **regularly manure your lawn** with a suitable Grass Manure, and the very best preparation for the purpose is

PEARSON'S ANTI-CLOVER MANURE

which will discourage the growth of clover and weeds and will encourage the finer grasses.

THOMAS GREEN & SON, Ltd., Smithfield Ironworks, Leeds, and New Surrey Works, Southwark Street, London, S.E.1.

The Twin Flower.—The Twin Flower of northern forests, *Linnaea borealis*, is the delight of all who can please its capricious nature and the despair of all to whom it will offer no response. Yet it is not as difficult a plant as many alpine. What it chiefly needs is a cool root-hold in a sweet old vegetable mould and, if possible, a half-buried and mossy decayed stump over which it can send its prostrate trailing growths which, root as they proceed. A half-shaded or quite-sunless spot appears to suit this plant best, although when established it will often do well in full sun. Frequent sprayings during the first summer, with shelter from parching winds, are undoubtedly helpful. The two flowers, which are borne on short, erect stems at intervals along the creeping branches, are a delicate rose pink and indescribably dainty. *L. americana* (*canadensis*) has rather larger blossoms of a slightly deeper colour. This form which, by the way, is more amenable to cultivation, flourishes all through the more westerly woods of the Canadian Rockies and extends right down to the sea in British Columbia making any moist and mossy place its home.

Potentilla rupestris.—Though rare as a native, being found only on one or two limestone elevations in Western Britain, this *Potentilla* has been brought to our rock gardens from the Alps and won a foremost place among the best of its race. From a short, woody stock it produces a bold tuft of fresh green leafage, from the centre of which the 12 in. to 18 in. flower-stems rise in the later summer. These bear at the tips of their many branches large, pure white, golden-centred flowers which at first glance recall those of the Grass of Parnassus. Once established in a warm and sunny, freely drained "pocket," with a lump or two of old mortar at the root, *P. rupestris* will carry on for many years without any attention whatsoever. *P. pygmaea* of catalogues appears to be none other than a miniature form of the above and a very dainty little plant it is.

An Elegant Woodland Plant.—For a cool soil, or bog, with or without shade, *Gillemia trifoliata* is a plant whose grace of form will win it a place among the choicest *Spiraeas*, to which it bears some affinity. This is a herbaceous perennial, quite hardy, growing up to about 2 ft., and making a bold mass of its three-lobed leaves and many-branched stems which terminate in the flower sprays. These latter are not showy, nor are they produced in any great abundance, but the little white stars are very refined and delicately beautiful.

Potentilla nepalensis Willmottiae.—It is only on account of its long blooming season this *Potentilla* would rank high among rock plants, for it is the first to come into flower in early spring, and carries on until nearly Christmas. It has, however, other claims to attention, among which is the lovely cherry red of its wide-open flowers with their eyes of jet set off by anthers which sparkle with gold dust. *P. Willmottiae* is, moreover, very easy to please, asking no more than a sunny spot in any free soil, and there it will prove quite hardy and permanent. It is as neat and orderly in shape as it is beautiful, and seldom exceeds about 6 ins. in height.

A Good Yellow Foxglove. There is much to be said for the yellow Foxglove, *Digitalis ambigua*, as a plant for the sunny or shady border, or for naturalising in the woodland garden or shrubbery. Though much lower in stature than the common native species, *D. ambigua* is very rigid and erect, not given to being blown over, nor does it look shabby when the bells begin to fall. The prettily tapered spikes (about 10 ins. rise from a tufty rosette of long, pointed leaves of a rich green, and smaller leaflets of the same narrow form grow upon the lower parts of the flowering stem. This

species has, moreover, a perennial nature to recommend it, and it will, as has been suggested, produce self-sown seedlings in any suitable situation. The flowers are a good size and much superior in colour to those of *DD. lutea* or *leucophylla*.

United Horticultural Provident Society.

The Monthly Meeting of the United Horticultural Benefit and Provident Society was held in the Royal Horticultural Society's Hall on Monday, February 12th, Mr. Charles H. Curtis presiding. The Chairman reported the death of the Treasurer, Mr. Thomas Winter, and votes of sympathy to the widow and daughter were passed in silence. Mr. Arthur Bedford, being appointed Treasurer,

resigned his position as committeeman and Vice-Chairman, Mr. W. H. Divers being elected Vice-Chairman *pro tem*. Final arrangements were made for the Annual Meeting on March 12th, at which Mr. Charles H. Curtis will preside; members are urged to attend that evening.

FORTHCOMING EVENTS.

February 27.—Royal Horticultural Society's Fortnightly Meeting.—Lecture at the University College, Gower Street, London, W.C.1, at 5 p.m., by Dr. W. B. Brierley, on "Soil Fungi."

March 1.—Lecture at the University College, W.C.1, at 5 p.m., by Dr. W. B. Brierley, on "Soil Fungi."

35th SEASON.

CATALOGUES, PLANS, AND ESTIMATES ON APPLICATION.

ANSWERS TO CORRESPONDENTS

THE GREENHOUSE.

ARUM LILIES UNSATISFACTORY (T. S. C. Hunt).—

The source of the trouble with the Arum probably lies much lower down than the foliage, and is no doubt to be found in the rotting of the corn through the attack of a soft rot bacterium which also attacks various widely grown crops like Turnips. The organism is often distributed in water used in watering plants, and attention to securing a pure water supply is very important. The corns should be examined and all parts showing signs of rotting should be cut away and burnt, while washing in a weak disinfectant might be an advantage. They should be repotted in fresh soil and in sterilised pots with sterilised crocks. Sterilisation of pots and crocks could be effected by boiling in water.

FRUIT GARDEN.

GOOSEBERRY BUSHES DISEASED (M. of M.).—

The Gooseberries were heavily infected with American gooseberry mildew, and should not have been sent out from the nursery. The distribution of such bushes rightly comes under the ban of the Diseases and Pests regulations, and the nurseryman should be called to account for sending them out. The introduction of them to the garden is a menace to the health of other Gooseberries there. The bushes should be cut back severely and all prunings burnt.

HOW TO TRAIN A NEWLY PLANTED CHERRY TREE (Curious).—As the tree was planted just before Christmas, the roots and soil will have settled down, and the branches may be fastened to the wires or nailed to the wall. The Morello Cherry bears its fruit on the young shoots—those grown during the past year—so these must be retained and tied in. Simply cut out any surplus shoots that would cause overcrowding.

KITCHEN GARDEN.

GROWING CARROTS IN A FRAME (A. L. M.).—We

presume that our correspondent sowed seeds of an early variety—one suitable for frame culture. A gentle heat from a bed is the chief inducement to rapid growth. A little air must be admitted at all times, except when frost occurs. If the glass lights are kept closed too much top growth will be made at the expense of the roots. The early varieties rarely possess large leaves and, at the stage when the first young leaves form, the growth of the plants seems to be very slow. As the days lengthen and the sun gains power the Carrots will grow more satisfactorily.

MISCELLANEOUS.

DAFFODIL BULBS ATTACKED (S. L.).—The bulbs

sent for examination are attacked by eelworm. They should not be planted out, as they are likely to infect the soil, but would be better burnt.

SEEDS FOR EXAMINATION (Mrs. W. Cheshire).—

The sample sent for name and stated to be the seeds of the New Zealand Palm consists of a mixture of fruits and seeds. The latter, which are black, are almost certainly those of a species of *Cordyline*, probably *C. australis*, known also as *Dracaena australis*, which is a palm-like species belonging to the Liliaceae group of plants. The small fruit has not been recognised.

PLANT FOR IDENTIFICATION (W. F.).—The plant

sent for identification is *Billbergia nutans*. It is a native of Brazil, but will do well in a warm greenhouse or room. The most suitable soil is a mixture of peat, leaf-soil and loam in equal parts, to which has been added some sharp sand. Free and perfect drainage is necessary for these plants, and a layer of moss should be placed over the crocks in the bottom of the pots to prevent the soil from working down among them. Little water is necessary, just sufficient to keep the soil moist.

Vesey's Patent Universal Spreader

This valuable and much needed Machine is adaptable for quickly and easily distributing all dry substance such as Manures, Lawn Sand, Lime, Common Sand, &c., &c., on Golf Links, Bowling Greens, Lawns, &c.

The Blue-Green Face in Church

You see, on Saturday he painted the fence blue and the hen-run green, and he had never heard of KIT! So there was no help for it. The colour came off his hands on to his face. It wore away in a week, but . . .

It was pretty while it lasted.

KIT'S work in life is to clean the hands when ordinary soap is not strong enough. Grease and oil and paint and tar—those are the things KIT loves to move in the twinkling of an eye. Yet the after-feel is just the same as after the morning wash with toilet soap. None of the awful smell of "turps," or the soreness of pumice.

And the speed! KIT is the rub-and-a-wipe-and-it's-over-soap!

Price 6d. per Tin.

KIT
is IT

the
speed
soap

KIT. 5—55.

The Silver Medal Horse Shoe Boiler

MAKE THE MOST OF YOUR SMALL GREENHOUSE NOW and instal a "Horse Shoe" with Pipes. It is the best for heat maintenance after hours of inattention and burns least possible fuel. —Gardeners say so, and they ought to know.

38,000 Sold.

Used in the R.H.S. and Botanic Gardens and in many notable Gardens throughout the Country.

Booklet E and quotation post free.

Reduced Prices.

Chas. P. Kinnell & Co. Ltd.
Southwark St.
LONDON, S.E.1.

"Roses in December!"

in his garden. In yours, too—if you'll help your rose-bushes to grow hardy and robust. You can do it, as easily as he has, by using **ECLIPSE Fish Manure**. Your neighbours will crane their necks to take a look at your garden if you will learn this simple secret: It's the soil that's at fault nine times out of ten. The soil isn't rich enough. Strengthen it with **ECLIPSE Fish Manure**—and you will get hardy plants and rich deep-coloured blooms, in season and out of season.

ECLIPSE Fish Manure contains Phosphates, Nitrogen and Potash in their proper proportions. Being largely organic, it supplies humus to the soil.

PRICES:

7lbs. 14lbs. 28lbs. 56lbs. 112lbs.
26 4- 7- 12- 24-

Obtainable from all the leading Seedsmen, or if sent by rail 1/- per package to be added towards carriage.

WONDERFUL RESULTS

Obtained by using Wakeley's Patented Hop Manure. Read Free Booklet.

DIPLOMA AND MEDAL AT THE ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912.

Beware of imitations.
Genuine Only in Our Marked Bags,
Containing Guaranteed Analysis.

THE ORIGINAL
ONLY
RELIABLE AND
SUBSTITUTE
FOR
STABLE MANURE

SCIENTIFICALLY AND CHEMICALLY PREPARED in the form of a leaf-mould, ready for use at any time, in the same way, and for all purposes that stable manure is put. Goes further (4 bushels equalizing 15 cwts.), gives better results, is clean to handle, sweet smelling, and free from weeds, worms, etc.

EVERY DRESSING OF WAKELEY'S HOP MANURE enriches the soil with the Humus it contains, doing lasting good, quite unlike the ordinary chemical manures, which act only as stimulants, and which, by constant use, impoverish it.

Cash Prices (including bags): Small (about 1 bushel), 3/-; Large (about 4 bushels), 7/-; 5 Large, 33/9; 10 Large, 65/-; 20 Large, 120/-.

Carriage paid to any station within 25 miles of London, including delivery within free delivery radius of Railway Company: 6d. per bag extra for every 50 miles or part beyond.

A beautiful Free Booklet giving full particulars and testimonials sent on receipt of postcard.

The ATCO MOTOR MOWER

THE MOST EFFICIENT
MOWER ON EARTH.

Superiority in design and construction has won for the 1923 ATCO even warmer praise than did last year's model, which outsold all others on the market. Install an ATCO this season, and the money it saves will cover the money it costs.

CHAS. H. PUGH, Ltd.,

Whitworth Works,
31, Tilton Road,
BIRMINGHAM

The ATCO TURF CULTIVATOR (illustrated) is esteemed by leading Turf Experts as indispensable wherever there is grass. It aerates the roots, destroys plantains, daisies, and other fleshy-leaved weeds, levels turf, loosens and collects moss, makes coarse grass fine. It is the ONLY apparatus that ensures proper upkeep of turf, and it can be affixed only to the Atco Motor Mower.

Send for FREE BOOKLET offering FREE DEMONSTRATION on your own Grass, and furnishing many unsolicited testimonials.

PRICES.

16in.	£50
Cultivator £5 5 extra.	
22in.	£75
Cultivator £7 7 extra.	
30in.	£95
Cultivator £9 9 extra.

ROBERT SYDENHAM LIMITED,

BATH'S

Border Carnations,

Etc.

FOR PRESENT PLANTING

We make a great speciality of Carnations, and our stock is unequalled. The plants are very strong, perfectly hardy, and will satisfy the most fastidious buyer. The following sets are selected from our unsurpassed collection of 250 varieties and contain the cream of the new and older sorts.

SET No. 6.

Twelve extra fine varieties for 14/-, carriage paid.
Celestial—brilliant yellow self.
Delight—bright pink; grand form.
Elaine—a grand white; perfect form.
Gordon Douglas—glowing crimson.
Salmon Clove—rich salmon-pink; fragrant.
Rosa Bonheur—yellow, suffused crimson.
Caprice—pink, mottled red.
Centurion—yellow, splashed scarlet.
Ariadne—bright heliotrope; extra.
My Clove—apple-blossom, shaded helio.
Isolde—raspberry-red; extra.
Glow-worm—brilliant scarlet; dwarf grower.

SET No. 7.

One dozen choice varieties for 10 6, carriage paid.
Beau Nash—charming shade of rose.
Glamour—large yellow self.
Innocence—a lovely blush-pink.

Bookham Clove—bright crimson; fragrant.
Climax—buff, suffused old rose.
Trojan—glistering pure white.
Dignity—a lovely deep shrimp-pink.
Lord Tennyson—yellow, edged rose.
Duchess of Wellington—deep lavender.
Queen Alexandra—buff-yellow; very free.
Red Knight—bright salmon-scarlet.
Santa Claus—yellow, edged purple.

BATH'S POPULAR SET

of 12 fine named varieties of Carnations and Picotees.
 Price 8 6, carriage paid.

The three above Collections complete for 31/-, carriage paid

BATH'S Gold Medal PÆONIES

Pæonies are the most gorgeous of all garden flowers. They are exceedingly hardy, and when once established require less attention than almost any other plant. Many of the blooms of the following varieties attain a diameter of 10ins. and nearly all are beautifully rose-scented.

Twelve glorious richly fragrant varieties for 22 6, carriage paid.

SET No. 3.

Albert Crousse—pinkish-blush; enormous flowers.
Golden Harvest—blush, white centre, tipped red.
Duchess de Nemours—snow-white; free.
Festiva Maxima—pure white, tipped purple.
Marie Lemoine—pure white; late.
Mme. Calot—white, tipped rose; extra.
Mons. C. Leveque—a lovely silvery-blush.
Dainty—rosy-blush, showing golden anthers.
Solfatore—beautiful primrose-yellow.
Mme. Ducet—soft salmon, with silvery shading.
Victor Hugo—brilliant amaranth; delightful colour.
Reine des Francaise—outer petals rose, white centre.

SET No. 4.

Our selection of 12 very fine named varieties, mostly fragrant, for 15/-, carriage paid.

BATH'S GOLD MEDAL DELPHINIUMS

These plants are remarkably handsome in the border, and during the early summer and autumn the bold and stately masses of brilliant blue and purple produce a striking effect unequalled by any other flower.

SET No. 2.

One doz. extra fine varieties for 21/-, any 6 for 11/-, carriage paid.

Arnold Bocklin—brilliant gentian-blue.
C. W. Matthes—rich pure blue; light and dark stages.
La Tendresse—light blue and mauve.
Willy O'Brien—pure cornflower-blue, mauve centre.
Turquoise—pure Cambridge-blue, dark eye.
Rosenlust—light mauve, edged Cambridge-blue.
King of Delphiniums—gentian-blue and plum, white eye.
The Alake—intense dark blue, violet centre.
Zuster Lugten—pure Cambridge blue, silvery shade.
Roselare—cornflower-blue, tinted ageratum-blue.
K. T. Caron—gentian-blue, suffused mauve.
Ida R. Elliott—dark cobalt-blue, amethyst centre.

BATH'S POPULAR SET

of 12 fine named varieties Delphiniums for 10 6, carriage paid.

[MARCH 3, 1923.]

LILY PICTURES IN THE GARDEN

THERE are some garden pictures that one never forgets! It is years ago now that I left a grey old West Country house and crossed the smooth, closely mown lawns sloping gently to the banks of a gurgling brook, that gave the limit to the garden and the beginning to the wild. It was spanned by a bridge, if an affair of rough planks can be dignified by a name that conveys an idea of something so much more elaborate. Beyond it a brown track wended its way through odorous stretches of wild Mint towards an opening in the thin woodland that skirted the banks of the stream, offering a note of invitation to the unknown beyond. It was late in the day, and the boles of the trees rose dark against the western sky, aglow with the warm colour of an early autumn sunset.

Stretching westwards from this opening was a long glade that had evidently been cleared by some garden-lover endowed with that prophetic vision that is essential to success in all garden developments. It was not too early in the year for a few leaves to rustle slowly earthwards, and stray patches of bracken had already begun to take on that golden tint that precedes the ruddy brown of later days. Here and there throughout the clearing broad masses of Azaleas had been planted, and their foliage was now ripening to its fall. In early summer their wealth of colour had taken sole possession of the scene, but now, even that enchantment was rivalled by a climax of colour that seemed to glow in sympathy with the glory of the sunset.

Other vegetation there was, the dying purple of heather, the brown-red tints of Andromedas, the dropping fire of Maples, scattered masses of Loosestrife and Willow Herb along the woodland fringes, with a few purple flowers still straying among the warm browns of the ripened foliage, and somewhere in the shadows glowed radiantly some berried plant. Spindle Wood, perhaps. But the glory of the picture was not all in the riot of autumn-tinted foliage, nor in the deepening shadows of the woodland, that enclosed the scene on two sides, nor in the ever-changing wonder of the

western sky, but in all these, and the gorgeous masses of Tiger Lilies that lifted their orange splendour at irregular intervals throughout the picture. On through the glade the vision swept, and because the land beyond it fell away from sight, it seemed that the sombre track led on through the crimson, orange, auburn, sepia, purple and brown straight towards the iridescent sunset glow. As I looked the light passed slowly from the earth, the purples in the woodland deepened to darkness, and where but a short while ago all was rich colour and radiant light, now the scene was

one of shadowy indefinite forms. And it was well, for in that moment this garden effort had achieved its climax. In that moment Nature and garden art had united in one grand triumph, and never has mind of man reached a higher and truer conception of garden beauty than in that Orange Lily garden.

This is but one of many lily pictures, and with them all there is an indefinable charm that appertains to no other flower in the garden. For there is in the Lily itself a sort of regal atmosphere of enchantment that separates it from all other

flowers, whether it be the white purity of the Madonna, the orange splendour of the Tiger, the bloody wonder of the Scarlet Turncap, or the pearly delicacy of the Regal Lilies; all breathe a sweet freshness into the garden that they adorn that lifts them to an altitude far above their fellows.

"Lilies, the daughters of the dawn,
Folded in hoods of silver lawn
And shod with dim leaves green and grey;"

Why, all through the ages it would seem that there has been a custom to call any flower that possessed attractions out of the common, "Lily," until the common names of many flowers without the slightest claim of relation to the genus, are known as something-or-other Lily, as though in this genus floral evolution has reached its limit of progress, and sets the standard for the world of flowers.

The pictures that can be created in the garden with Lilies are many, and the positions in which they can be grown successfully as numerous. But of all these none offers the charm of association that is obtained by growing them in a setting of foliage of shrubs or trees, in those parts of the garden that form the link between the imperative formality of the garden near the house, and the wilder beauty of nature beyond the garden boundaries. Woodland walks, where in the half shade many varieties love to grow, and where the falling leaves have from year to year enriched the soil and rendered it light and open, is an ideal place for them. Planted among Azaleas and Rhododendrons they are particularly happy because the soil that suits the one is

THE SPLENDID ROYAL LILY, *LILIUM REGALE*, AND
L. WILLMOTTIÆ.

exactly what the other loves. Nothing could provide a more thrillingly beautiful picture than a mass of the easily grown *Lilium regale* planted in such a position. Flowering in July it fills in a gap after the earlier *Rhododendrons* are over, and indeed there are few that are planted in the average garden that are not over long before this period. Year by year the bulbs are getting more plentiful, and it is highly probable that if there had been no Great War, this would have been one of the best known, and most frequently cultivated Lilies in the garden by this time. For one thing it is easily raised from seed, and often flowers in the second year, and certainly in the third year from sowing. Perhaps the greatest charm of the flower lies in the pearly texture and the beautiful pink tint that creeps through the white, owing to its being externally coloured with a gradually diminishing shade of red-brown, which shows through its translucent segments.

Another Lily that is essentially for woodland planting is the towering Himalayan Lily, *L. giganteum*. The great mistake in planting this Lily, that is made annually by the impatient, is the using of very large bulbs, and it makes some enormous ones, too. Large bulbs make growth freely enough in the earlier stages, but do not make a corresponding quantity of root wherewith to sustain such luxuriant growth, and in consequence, unless conditions are exceptionally favourable, one finds them reaching a height of several feet in a very short space of time, and then ceasing to grow, finally collapsing in ignominious failure to sustain their early promise. Planted, however, in moderate or even small-sized bulbs, among shrub-berries, or on the fringes of woodland, where the soil is well drained, but not dry, they possess no

attributes that make them difficult of cultivation, but many that make them highly desirable.

It is a far cry from the giant just mentioned, with its 12 ft. to 14 ft. of majestic stature and numerous flowers, to the delicate little pink *rubellum*. Delicate in colour only by the way, as it is one of those that naturalise well under reasonably favourable conditions, and its fragrant rose-pink flowers seen rising from the young fronds of ferns, in their soft green tints during May are indeed a revelation of pure beauty. Ferns and Lilies! is there any combination that offers so subtle a suggestion of garden delight? I wish I could say that the beautiful *L. Krameri* was as persistent as *rubellum*. They resemble each other, although *Krameri* is much the better flower of the two, but it cannot be regarded as so permanent a planting. Plenty of sand in the soil appears to be the secret of growing it well, and I remember a box of bulbs that had been bedded in pure sand to keep them firm for late planting, and was overlooked. The result was a box full of really fine blooms.

As I am writing solely of Lilies for the outdoor garden, it is not necessary to notice such sorts as *sulphureum*, *nepalense*, *neilgherrense*, and other varieties that are not for the garden picture maker, but in at least one case the influence on outdoor Lilies has been felt. *Sulphureum* crossed with *regale* has produced some really remarkable results. The yellow interior of *regale* has been intensified, the long flower of *sulphureum* has been introduced into *regale*, height has been increased, and all the charm of *regale* remains emphasised and intensified in a race that flowers several weeks later, and has a remarkably robust constitution. Of the remaining Lilies suitable for woodland

planting, some in the more open portions, others in the more shady, are the *auratum*s, of which *L. auratum platyphyllum* is by far the noblest, the most robust and in every way the best. Given a fair chance in an open peaty root-run, where its roots are partially shaded by overhanging vegetation, it will produce magnificent stems that carry enormous flowers. Like all the *auratum*s its pungent, overpowering odour renders it a little too voluptuous for the small room indoors, but breathing its redolent perfume on the atmosphere of an August evening is a pure sensual delight. I have already mentioned the wonders of the Tiger Lilies in such conditions, and the best of them is, of course, *L. Fortunei giganteum*. It is in every way the tallest and most imposing of the group, and I have known it succeed for periods that have seen the disappearance of the *speciosum* group under the same conditions. It must not, however, be inferred from this that the *speciosum*s are difficult to grow in the average garden. Far from it! they are, indeed, among the most successful. Of the coloured forms *melpomene* and *magnificum* are the best, although the ordinary form, *roseum*, can be relied upon to produce some wonderful flowers. Of the whites, *speciosum album Kratzeri* is the best all-round variety for garden purposes.

Space forbids dwelling on the Martagon group although the English garden without its Martagon Lilies is an incomplete thing, and they succeed almost anywhere. The white form is beautiful indeed, but by no means plentiful. One of the most startling achievements of recent years is the result obtained at Sutton Court by the crossing of Martagon and Hansonii. The resulting race shows an almost inconceivable variation and among them are many that appear to be more

THE BEAUTIFUL FALL ORANGE LILIAM HENRYI.

THE SHADE-LOVING YELLOW AND CHOCOLATE LILIAM PARRYI.

vigorous than either parent, and with many new and delightful colour developments that will ensure for them an important place in the Lily world.

Among Lilies for the border, none are more attractive than *L. Henryi*. It is, perhaps, a little too tall to look comfortable, but there is a unique value in its rich apricot-yellow flowers and a grace of form in its curving reflexed segments that places it in a class entirely its own.

Of many other garden Lilies I cannot speak now, but there are a few by their constitution fitted for the moister places in the garden, by the stream side, in damp depressions along the woodland margin, and they have therefore a value all their own. *L. pardalinum* is one of them, a Californian species of which there are one or two varieties, and it will spread itself freely under satisfactory conditions, which are not in any way exacting. Its orange, crimson-spotted flowers are a joy in the July bog garden. *L. Parryi* is another moisture-loving species which is not always easy to obtain, but when it can be grown it produces a flower of a wonderful shade of yellow spotted with warm brown. *L. canadense*, the Canadian bog Lily is another that desires similar conditions and thrives well under them, and its brilliant orange-red colour is unlike any other. Of many of the very old Lilies I can say nothing now. Such are the *Madonna* (*candidum*), *croceum* and the *Yellow and Scarlet Turk's Caps*. Nor can I mention many of the new varieties, but I am writing for the ordinary garden and the ordinary purse, so it is as well that there is a limit to my space.

In all this world can there be one who, loving the beautiful things around, does not love Lilies? I believe not! but if there is, then for that one

there remains a greater joy than has hitherto fallen to his or her lot. For such coldness can only be due to lack of acquaintance with them, and with knowledge will come a full appreciation of their grace and beauty. I have only touched the fringe of all that this wonderful flower world contains, and have only indicated a fraction of the garden pictures of which they are capable of producing. Do you as an artist want inspiration for the interpretation of pure grace and elegance of form? as a poet, a symbol for all that this world holds of the true and good? as a humble worshipper at Nature's altar, the supreme satisfaction that comes from the love of her finest and noblest achievements? as a preacher or teacher, lessons for use in everyday life?—you can find them all in the Lily. Nor can you be in any way original in this, for poet, painter, sculptor, teacher, throughout the ages have been before you. Throughout all time, it is the flower that most consistently have noble men laid at the feet of beautiful women.

GEORGE DILLISTONE.

THE INVALUABLE GLADIOLUS

PLANTING-TIME has come round again for the late-flowering Gladioli. The early-flowering *Colvillei* and *Ackermannii* varieties are, of course, best planted about November and given protection in severe weather. It is therefore of the late-flowering varieties I purpose to write to-day. The Gladiolus, at any rate in its best types, has a beauty of form and of colouring second only to that of the Lily. Its value in the garden scheme is thus at once apparent, but it has the advantage of being available for situations where no Lily would succeed. Since the corms only remain in the ground for a few months, there is no need to worry as to what may happen to the bed or border in winter-time. Neither flood nor vermin outdoors will disturb the Gladiolus, then safely stored away in a cool but frost-free place.

The Gladiolus likes a rich soil, but dislikes rank, unrotted manure. The land should be deeply worked, and if rather on the stiff side so much the better. It must be in good working condition at planting-time—it is better to wait a few weeks than to plant in soddened or lumpy ground. It is certainly wise to surround the corms with coarse sharp sand—very coarse silver sand is good. Mulching in dry weather and, when the spikes are developing, soakings of fairly weak liquid manure are beneficial.

The large-flowered *Childsii* hybrids are cheap to buy and excellent for massing in the herbaceous border. The same may be said of the brilliant scarlet *G. brenchleyensis*, which may also be used effectively in the wild garden. This is very effective when planted so that its spikes contrast with the greenish ivory bells of *Galtonia candicans*. A selection of cheap large-flowered sorts would include Halley, ruddy orange, blotched yellow;

Mrs. Frances King, bright salmon pink; Panama, deep rose, very large; Peace, a fine white; Princeps, scarlet, rather early; Baron J. Hulot, violet; America, soft lilac rose; Niagara, nankeen yellow, striped soft lilac; Glory of Holland, pure white; and Empress of India, darkest maroon.

Effective as such varieties are when massed, some of the beauty of the individual spikes must necessarily be lost where more than half a dozen or so are grown together. The choicer and more elegant varieties certainly look best when grown in groups small enough for the carriage of the individual plants to be observed. This particularly applies to the graceful *primulinus* hybrids. In this (*primulinus*) section are to be found the most beautiful Gladioli yet in existence—exquisite in form, glorious in colouring, coyly gracious—altogether charming. Numbers of beautiful varieties have been described in *THE GARDEN* during the last twelve months and it is difficult to select a best dozen, but, taking price into consideration, the following twelve would be hard to beat. *Unsurpassable* is a tall variety with large wide-petalled flowers not inaptly described as of Caroline Testout colouring, *i.e.*, bright pink, shaded silvery white, but the colour is cleaner than in the well known *Rose*. *Alice Tiplady* is "everyone's favourite." The blossoms and spikes are shapely and the colouring is orange-saffron. The best yellow to date is probably *Butter Boy*, but until it becomes cheaper, either *Anita* or *Canopus* will give pleasure; both are delightful. We cannot omit *Linton*, with

charmingly ruffled petals; the upper segments are salmon pink deepening to the edge and the lower ones golden yellow veined rose. The brilliant orange *Niebe* must not be left out nor the exquisite *Nydia*. The latter is an idealised apple blossom pink—no apple blossom ever had quite so much

GLADIOLUS UNSURPASSABLE, OF CAROLINE TESTOUT COLOURING.

salmon shading—and of beautiful form. For its dazzling colour *Scarletta* must be included; the flowers are scarlet outside and fiery cinnabar within, a brilliant and remarkable variety. *Woodcote*, one of the fine varieties raised by Major Churcher, is perhaps the best *primulinus* hybrid raised in Britain; it compares very favourably, in fact, with any in commerce. The colour is coral scarlet with a soft yellow blotch on the lower segments, and the shape of the flowers and their arrangement on the spike is all but ideal. At 2s. per corm or less most of us may aspire to grow this gem. *Orange Brilliant* is a small-flowered orange variety, very graceful and admirable for cut flower and quite cheap. Another variety by the same raiser (*Grullemans*) and also cheap shall have the tenth place. This is the soft pink *Maiden's Blush*. The deep yellow and orange *Enon* would have had earlier mention, but is slow to increase and consequently still dear. Perhaps the salmon buff *Cassandra* is eligible for the twelfth place in the writer's estimation, but it must be admitted that someone else might select a dozen and not include more than three or four of those mentioned, so wide is the selection available.

AMATEUR.

SOME MARSH-LOVING PRIMULAS-I

Primula sibirica and its Allies.

IN this extensive and popular family there are several groups of species which are readily distinguished from each other by their characteristic appearance, as well as by the various conditions under which certain species are found growing. In the alpine group the majority are rock-loving plants, growing in the stony crevices and on the rocky ledges of the mountains. Others are woodland plants, which delight in shady or half-shady situations, growing in rich soil composed mostly of humus. Then we have a very large group, to which *P. sibirica* belongs, the members of which grow in marshy ground or where there is always plenty of moisture. They are mostly of easy cultivation when given these conditions and are readily raised from seeds, which need to be fresh, otherwise they take a long time to germinate.

During the last few years many new *Primulas* have been introduced from Western China and the borders of Tibet. Among these are some which are closely allied to the older and better-known Siberian *Primula*, and which will flourish under the same conditions. Some of these are mentioned below. There are others which are not closely allied to *P. sibirica*, but which enjoy similar conditions under cultivation. These will be dealt with later.

P. sibirica has a very wide distribution in its various forms, occurring on all the Himalayan range from Western Tibet to China, and through North and Central Asia from Europe to North

and Arctic America. It is a slender-growing plant with a tuft of long stalked leaves from which the flower-stalk is produced. This varies in height according to conditions from a few inches to 1ft., and bears, usually, an umbel of rosy pink flowers in May. The type comes from Siberia, and has been in cultivation since the beginning of last century.

P. WARDII, here illustrated, is a later introduction from the marshes of Western Szechuan and the Tibetan frontier, being found by Wilson in Fa-chien-lu in 1903 at an elevation of from 9,000ft. to 13,000ft. It was exhibited at the Temple Show of the Royal Horticultural Society in 1907 as *P. sibirica* var. *chinensis*. More recently found and sent home by Forrest and Ward, it has turned out to be a most desirable plant. It differs chiefly from *P. sibirica* in its larger, more or rosy pink flowers and in the larger involucre bracts at the base of the umbel. Of robust habit, it grows from 6ins. to 1ft. high, and is very free-flowering, producing its blossoms in May.

P. CONSPERSA is also a recent introduction from Western Kansu, where it grows at an elevation of 5,000ft. to 9,000ft., and was found by Farrer and Purdon in 1915. It is a rather weaker-growing plant than the above, producing quite a mat of its tufted green leaves, from which slender stems arise to the height of 1ft. or more. The rich lilac flowers are borne in whorls, two or more on the same flower-stalk, according to the strength of the plant. In this country it flowers in April.

P. TIBETICA, also illustrated, is a native of the Himalayas on the borders of Tibet. It was originally found by Sir J. Hooker on the Sikkim frontier of Tibet some seventy years ago. Its introduction we owe to Mr. A. K. Bulley, whose collector, Mr. Cooper, found it in Bhutan in the Eastern Himalayas and sent seeds home in 1915. It is a high alpine species, growing at an elevation of 10,000ft. to 17,000ft. Closely allied to *P. sibirica*, it differs in having a shorter scape, while the pedicels bearing the individual flowers are very long. It is a charming little plant with its rose-coloured flowers having a yellow eye.

P. LOOZII is another little plant from Kansu. It is more closely allied to *P. farinosa*, and is characterised by having runners which produce offsets like a Strawberry. The leaves are covered with meal as in *P. farinosa*, while the flowers are of a pale lilac colour, borne in umbels on a stalk a few inches high.

P. INVOLUCRATA.—This is a well-known Himalayan plant which has been in cultivation for nearly eighty years. It is a good perennial, which increases freely when planted in a moist situation where water is within reach of the roots. In early spring the flowers are produced on slender stems 6ins. to 8ins. high. These flowers vary in colour from creamy white to pale blue, although the latter shade is rarer than the white. This species is readily increased by division in early spring or late autumn. One of the synonyms by which this plant is known is *P. Munro*. W. L. J.

LIKE A VERY FINE *P. SIBIRICA*, PRIMULA WARDII.

THE ROSE-COLOURED *P. TIBETICA*.

THE HERBACEOUS LUPIN

THE plants about which these notes will be written are listed in nurserymen's catalogues under *Lupinus polyphyllus*, but is perhaps safer simply to call them herbaceous Lupins, for many of them have, we know, "blood" of *L. arboreus*, and

embracing shades almost as vivid as the "electric" blues which a few years ago were fashionable for feminine wear.

The original rosy pink tones will probably be familiar to all readers. They are very pleasing when the blossoms first expand, but as the flowers go over the spike takes on a very unpleasing bluish tone. In some of the newer varieties this tainting has been largely overcome: so much progress has, indeed, been made as to warrant hope that this disagreeable fading colour may be entirely eliminated. Much deeper pinks have recently been produced; indeed, the variety *Downer's Delight* is much more strawberry red than pink, a colour, in fact, which would be useful in some places but is not an easy colour to combine with others. Besides these deep pinks there is now a new series, of which the colouring is a combination of pink and buff or pink and yellow.

Pure white varieties are now plentiful, so that in a long herbaceous "colour border" it is possible to use Lupins to provide early summer colour in every section. Individual tastes, too, can easily be suited. For those who like pastel shades they are there in plenty, while lovers of really robust colouring will find little lack.

Messrs. Clarence Elliott showed last year at the Royal Horticultural Society's Hall a very

beautiful strain with a great variety of colouring which was noticeably fragrant. Fragrance is a

very desirable attribute of any flower, and this strain well deserved the award of merit bestowed upon it. Messrs. Kelway and Son of Langport were one of the pioneer firms with this useful and beautiful flower, and some of their named varieties are exceedingly attractive. Mr. Geo. Downer of Chichester has a strain which every season seems to produce new and distinct varieties. Messrs. Harkness and Sons of Bedale also have their special strains. Their great speciality is in the yellow-pink and buff forms, to which reference has been made. In addition to the firms mentioned a number of Continental nurserymen are, and have been, working upon this flower, so that further great advances may be confidently expected.

The Lupin, though thong-rooted, is fairly easy to propagate by division. It is, of course, of the easiest culture from seeds, but there is with some of the newer shades small likelihood of the plants coming true to colour. Any decent garden soil suits these accommodating plants, which seem equally at home in herbaceous border or in the wild. They flower at the same time as the tall June-flowering Bearded Irises, and with their present range of colouring are exceedingly useful for associating with these gorgeous and very fashionable flowers.

There is, however, no particular reason why the Lupin should always "play second fiddle" to the Iris. The plant is not wanting in dignity. It is not very tall certainly, but it holds itself erect. The self-coloured forms when massed give a solid effect of colour which few Bearded Irises could approach. (Not all Bearded Irises flower like *Caterina*, for example, or a different tale might be told.) The value of *Lupinus* in the semi-wild garden was demonstrated by the pictures published last year in *THE GARDEN* (July 1, page 315) of semi-wild gardening at Cator Court, Devon. There they are associated very effectively with the single white form of the Rocket (*Hesperis-matronalis*).

Especially if restricted to one colour, or one colour and white, the Lupin is admirable for massing on the edge of woodland. It looks almost as "at home" and natural there as the Broom or wild Mallow. Some of the very pleasing soft lavender shades are perhaps best for such groupings, but the pink strains are unexceptionable also.

When all is said, the list of hardy June-flowering plants is not a long one, and no garden to-day can afford to be without these herbaceous Lupins.

THREE TYPICAL HERBACEOUS LUPINS.

there is every reason to suppose that other species have been pressed into service to produce the wide range of colouring which now exists. Indeed, we have heard it said—but perhaps it is better to let such parentage problems rest. As there are no patent rights in plant production, the raiser's only resource is to "keep his mouth shut."

Not so many years ago the Lupin was a rather neglected herbaceous plant; indeed, it was worse than neglected—for, owing to changing fashion, extremely worthy plants become neglected it was despised. The colourings then commonly seen were a dismal purplish blue and an even more dismal dirty white. True, even in those days a rich deep blue almost devoid of purple was in existence and a moderately pure white, but they were rarely seen. Then, from more than one source, pink varieties made their appearance and created something of a sensation. The break in colour aroused interest in the plant, and to-day we are on the threshold of a Lupin "boom," if, indeed, it has not set in.

From a delicate creamy mauve to the strongest and richest blue-purple and from an equally faint blue to a deep rich "navy" practically devoid of red runs the colour range in blue tones,

LUPINS IN THE BORDER.

PERPETUAL-FLOWERING PINKS

ONE of the great achievements of the modern hybridist is to extend the flowering season of a number of the most popular flowers. A decade ago the Rose was practically a summer-flowering garden plant. Now its blossoming period extends to a time when winter puts an end to all outdoor flowering.

The average person is apt to regard the Pink as a summer flower with a very limited blooming period. The white variety Mrs. Sinkins is very familiar, but apart from its fragrance, its splendid habit and the decorative value of its fine, glaucous foliage in winter, it has little else to recommend it. It is a ragged-looking flower and nearly always

Since then many new and more beautiful varieties have been evolved. There are many new colours already in commerce, several of them now at a popular price. All are of easy culture, and they are readily propagated by means of layers or cuttings.

A SELECTION.

The following are likely to become the most popular:

Model has flowers faultless in form, the edges being as if dressed. It is a soft rosy pink with a deep red base, and apart from its exquisite shape it is very free-flowering.

Queen Mary is another rosy pink of different form. The edges of the petals are not quite as

cleanly cut as those of Model, but they are not far from the ideal. A deep crimson colour is at the base of the petals, and this gives the flower a rich and telling appearance. The calyx is very strong and, what is also important from a decorative point of view, the blooms can be cut with stems from 15 ins. to 18 ins. in length.

Mrs. G. Walker is a bright pink with a dark rosy red base. It has a splendid constitution, and it is remarkable for its floriferous character. It is very highly perfumed.

Victory is a deep ruby crimson quite unique in colour. It is also very free flowering, has the clove fragrance very pronounced and is a good doer. These four varieties have all received an award of merit.

Three other kinds that have been much admired at the shows during the past year are Sweet Nell, a soft rose with a deep red centre; Gertrude, a finely formed rosy mauve with a purple base; and The Imp, a dark crimson self.

The remaining standard varieties include Dickie Felton, salmon pink; Comedy, rose mauve; May Queen, bright pink; Simplicity, cherry red; Imperial, a brilliant crimson-scarlet of dwarf habit; and Ruby, of the same character and a colour described in the name.

SOME NOVELTIES.

Notable new creations include Bridesmaid, a magnificent flower of salmon blush colouring with a deeper centre; Lord Lambourne, a distinct shade of deep rose; and Red Indian, another unique colour, a pretty shade of old rose. All these received the award of merit at the Chelsea Show of 1922.

A sensational colour break has occurred in the newer varieties in the form of an orange scarlet self of vivid hue. It has been named Fire King, and promises to be one of the finest Pinks that

has so far been produced. Every up-to-date flower-lover should try some of these splendidly free and continuously blooming fragrant hardy flowers.
NORMAN LAURET.

SMALL-GROWING SHRUBS

IT is a very common mistake to plant trees and shrubs in gardens without due consideration being given to the character of the shrubs when they become fully grown and the general effect they will have then. In my youth I saw old experienced gardeners making this mistake. It had been a failing with their forebears, too, and it is still in evidence. To digress just a little. How many otherwise charming carriage drives and main pleasure paths are spoiled through the too-close planting of trees and shrubs to them? Thousands of finely grown trees—mainly evergreen—have been spoiled through being cut back indiscriminately to prevent the closing-up of the passage between them.

I have recently inspected a number of villa gardens in and near to a beautiful town. Quite 90 per cent. of those gardens contained shrubs too large for them. Many shrubs had been hacked about to enable the owners and their visitors to pass by them. Their general appearance had become unsightly, many were quite out of character and others were dying.

In large gardens it is absolutely necessary to "fill in" with temporary shrubs and trees; in small ones it may be advisable to plant, temporarily, certain shrubs. But those specimens intended to remain permanently should always be planted with due consideration as to their ultimate size, so that there may be full development consistent with the space available, and that the natural beauty of each may be seen to the best advantage.

If there is only room for a dozen shrubs, why plant two dozen, unless it is intended that the surplus ones shall be removed in due course? Unfortunately, there is much reluctance to part with them and they are left until they cause damage to the choice specimens.

SOME DECIDUOUS FLOWERING SHRUBS.—The following are suitable for small gardens where they may grow to full size without undue mutilation. *Cydonia Maulei superba*, *Daphne Mezereum*, *Escallonia Philippiana*, *Forsythia suspensa*, *Hydrangea paniculata grandiflora*, *Magnolia stellata*, *Philadelphus Lemoinei*, *Prunus japonica flore albo pleno*, *Ribes sanguineum atropurpureum*, *Robinia hispida inermis*, *Spiraea Menziesii triumphans*, *Sophora viciifolia*, *Lilacs*, *Viburnum tomentosum plicatum*.

DECIDUOUS FLOWERING TREES.—*Æsculus carnea* Briotii, *Amelanchier canadensis*, *Catalpa bignonioides*, *Double-flowered Thorns* (white, rose and scarlet), *Laburnum alpinum*, *Magnolia conspicua*, *Prunus Amygdalus* (Almond), *P. Avium flore pleno* (double-flowered white Cherry), *Pyrus Aria majestica*, *P. floribunda atrosanguinea*, and *P. spectabilis flore pleno*.

SOME EVERGREEN FLOWERING SHRUBS.—*Berberis stenophylla*, *Chiosya ternata* (for sheltered borders), *Kalmia latifolia*, *Olearia Haastii* (does well in dry borders), *Rhododendrons*, *Veronica Traversii*, *Viburnum Tinus* (*Laurustinus*), *Yucca glottosa* and *Y. recurvifolia*.

SOME SHRUBS AND TREES BEARING FRUITS.—*Arbutus Unedo*, *Barberries*, *Thorns* in variety, *Euonymus europæus*, *Hollies* in variety, *Pernettias* in variety, *Pyrus* in variety, *Sambucus racemosa*, *Skimmias* and *Viburnum Opulus* (wild Guelder Rose). *Fuchsias* should be more freely planted in small gardens, especially *FF. Riccartoni*, *globosa* and *macrostemma*.
GEORGE GARNER.

DIANTHUS HERBERTII MAY QUEEN.

bursts its calyx when opening. It has a very short blossoming period. This latter failing is the chief drawback of the Laced and Self Border Pinks. They are for such a long period flowerless plants.

Some years ago Mr. C. H. Herbert succeeded in raising a new type with an extended blooming period. By crossing two of the Laced Pinks, Arthur Brown and Robert Haulgrave, the former with purple lacing and the latter with red, he produced a variety which he aptly named Progress.

THE PIONEER OF THE NEW RACE

This new variety was of lovely rosy mauve colouring. It was a flower of perfect form and had a non-splitting calyx. The plant had a vigorous constitution and the flowers were carried on strong stems so that no staking was necessary;

THE SMALL-LEAVED RHODODENDRONS

Among the very many new Rhododendrons introduced from China during the last twenty-five years no section is more distinct and valuable than that comprising the dwarf alpine species.

IN every rock garden of any extent at all dwarf shrubs can be used most effectively. If these shrubs are attractive when in flower so much the better. Quite a considerable number of the newer dwarf-growing Rhododendrons are, therefore, admirable for the rock garden. Another important consideration is that some of the Rhododendrons bloom rather early, and the sheltered nooks available in most rock gardens are ideal places for them.

With the diminished possibilities as regards expenditure, largely increased attention is being given to the outdoor garden and particularly to the choice shrubbery. In such a shrubbery, if the soil is lime-free, Rhododendrons of comparatively dwarf growth fittingly find a place.

Though the liberal heating of so many green-houses is being abandoned, their use as cold houses for the protection of early-flowering Rhododendrons is deserving of attention. The taller-growing bushes can be planted out in borders and rockeries formed for the dwarf species, while some may also be cultivated in pots on the stages and moved outside in summer from, say, June until September or October.

R. BRACHYANTHUM is a Yunnan species introduced by Mr. George Forrest in 1906. He describes it as a shrub 2ft. to 5ft. high growing on the Tali Range, West Yunnan, at 10,000ft. to 11,000ft. elevation. The oblong-lanceolate leaves are 1½ins. to 2½ins. long and up to 1in. wide. The sulphur

yellow flowers are bell shaped, up to ¾in. long and the largest blooms 1in. across. The flowers are borne in terminal clusters of three to six or eight blooms, each with a large pale green calyx suggestive of *R. glaucum*. The flowering season is June. This is a charming plant and evidently quite hardy.

R. FLAVIDUM is a very dainty shrub for sheltered positions in borders and the rock garden, as the flowers open during March and early April. It is a native of Western Szechuan, discovered by Soulié and named by Franchet, but for its introduction to our gardens we are indebted to Mr. E. H. Wilson. He collected seeds in 1904 and again in 1908, describing it as common in the alpine regions around Ta-chien-lu at an altitude

THE SPLENDID WHITE FORM OF RHODODENDRON MOUPINENSE.

RHODODENDRON INTRICATUM.

of 10,000ft. to 12,000ft. When first exhibited by Messrs. James Veitch and Sons, Mr. Wilson's plant was named by Dr. Hemsley, *R. prinulinum*, but it was subsequently identified as the species collected by Soulié and named *R. flavidum*. Mr. Wilson found wild plants up to 6ft. high, but its present rate of growth with us suggests that these must be very old specimens. Bushy plants 1ft. to 2ft. in height with small scaly leaves and primrose yellow blossoms 1in. across being the average.

R. HIPPOPHAEOIDES is one of the best half-dozen small-flowered and small-leaved evergreen Rhododendrons of recent introduction. It is a much-branched, rather upright-growing twiggy shrub 3ft.

to 4ft. or 5ft. high. There is considerable variation among the seedlings in the colour of the 1in. wide flowers, which are mauve, lavender or purple blue, bluish rose or rosy pink. These are borne in clusters of five to seven or eight at the ends of the shoots. This species seeds freely in gardens, and is also readily propagated by cuttings. In 1913-14 Mr. Forrest collected seeds in five districts of Yunnan at altitudes ranging from 10,000ft. to 14,000ft. Mr. Kingdon Ward also collected this species in 1913 in the Chung River Valley, Yunnan. It is a useful companion plant to *R. racemosum*.

R. IMPEDITUM is the correct name of the dainty purple-flowered alpine Rhododendron first introduced from Western China by Mr. George Forrest in 1911, when it was named and distributed as *R. fastigiatum*. It resembles *R. intricatum*, which, however, has the stamens within the corolla tube, while those of *R. impeditum* are distinctly protruding. *R. fastigiatum* is more open in habit, seeds freely and flowers about three weeks later than *R. intricatum*. Seedlings flower when two years old; in fact, when first introduced, several eighteen months old plants opened flowers in the autumn of 1912.

R. INTRICATUM.—This was the first of the purple-flowered dwarf alpine Rhododendrons introduced from China to flower in our gardens. Collected by Mr. Wilson in Szechuan at 11,000ft. to 15,000ft., it is perfectly hardy, but, flowering in April, should be planted in sheltered positions. Averaging 6ins. to 9ins. in height, the tufts increase in size, and if liberally mulched with leaf-mould, root freely into it and can be readily propagated by division. *R. intricatum* does not produce seeds with us, but cuttings on plants grown under

glass root readily in a propagating frame, for which purpose it is easy to lift a plant or two with good balls of soil.

R. MICRANTHUM. This is one of the most distinct of the small-leaved species. With its many-flowered racemes of small white blossoms the plant is not infrequently mistaken for a *Sedum*. It forms a bushy evergreen at present 2 ft. to 3 ft. high, but will no doubt grow taller. The two outstanding characters are that it flowers in June and is very hardy, being one of the strictly limited number of evergreen Chinese *Rhododendrons* hardy in the Arnold Arboretum, U.S.A. It is of wide distribution, being found in North and Central China and Manchuria. Our plants were raised from seeds collected by Mr. Wilson in Western Hupeh.

R. MOUPINENSE is this year flowering in February. No doubt because of the mild weather it is several weeks earlier than usual. There are pink and white flowered forms, the latter being the more common and perhaps the more beautiful. In habit, foliage and flowers (about 2 ins. across) *R. moupinense* suggests the Indian *Zinias*, so popular in our greenhouse. Being early and free-flowering I throw out the suggestion that it is worthy of cultivation for cool and unheated greenhouses. Outside, this *Rhododendron* should be planted in very sheltered positions. It is a native of Western China and Tibet.

R. NERIFLORUM is another charming and distinct addition to our cultivated *Rhododendrons*. In a wild state it must be a variable plant, being described as 2 ft. to 8 ft. high, the colour ranging from deep rose to deep crimson and flowering from April to June or July. One of the plants we had flowering at Kew was as rich in colour as *Thomsoni*. The bell-shaped flowers, eight to twelve or more in number, are borne in a terminal cluster. It was introduced from Yunnan by Mr. Forrest in 1906. Growing at 9,000 ft. to 12,000 ft. elevation, it should be hardy in most gardens.

R. OLEIFOLIUM. This species in some respects resembles (and for that reason is much confused with) the beautiful *R. racemosum*. The important distinction is that in addition to having larger leaves and flowers, the blossoms of *R. oleifolium* are borne singly or sometimes in pairs in the leaf-axils, whereas with *R. racemosum* there is usually quite a crowd of blossoms in each axil. Nevertheless, when raising seedlings the two vary so much it is sometimes difficult to say where one begins and the other ends, though typical plants of both are easy to distinguish. The flowers are white with a rose tint.

R. RACEMOSUM is one of the best known and most useful Chinese *Rhododendrons*. For massing in borders and for lawn beds it is a valuable evergreen shrub covered in April and May with quantities of small pink-tinted white blossoms. Produced in terminal and axillary racemes, vigorous plants may carry growth wreathed with 1 ft. to 2 ft. lengths of blossoms which are delightful to cut for decoration indoors. The first seedlings were raised in the Jardin des Plantes, Paris, in 1889 from seeds collected by Pere Delavay. Later introductions shew considerable variation in the rose and pink tints of the blossoms, particularly in the bud state, and there is also a white variety occasionally among the seedlings. One thing which troubles growers of numbers of plants is that they produce seeds very freely, which, if left to mature, considerably weaken the new growths. If the plants are to give of their best the removal of the seed pods is imperative.

R. SARGENTIANUM is another dwarf alpine species producing in May small terminal clusters of six to twelve pale yellow blossoms. It is a gem for the rock garden or the narrow border of choice shrubs.

R. SCINTILLANS is a very distinct species of the "fastigiatum" group. Its notable characters are a twiggy growth 2 ft. to 3 ft. or more in height, rich purple blossoms in April, and charmingly prominent golden brown anthers. Introduced by Mr. Forrest in 1913 from Yunnan, this promises to be a charming and valuable introduction.

R. SOULIERI in flower is one of the most captivating and distinct, with its glaucous leathery foliage and open saucer-shaped blossoms. One form has delicate rose pink flowers, the other waxy white flowers. Mr. Wilson, who introduced it first in 1905, describes *R. Soulieri* as a common evergreen shrub in Western China near Tachien-lu. Under cultivation, plants are not proving easy to manage, but as it is such a distinct and fascinating

Rhododendron we must keep trying plants under varying conditions until they grow with native luxuriance. Two plants grew and flowered well and produced seeds in shady woodland until the dry summer of 1921, but the liberal watering then necessary on our dry soil, despite a heavy mulch of leaves, was apparently unsuitable and both have since died.

R. WILLIAMSIANUM is of spreading prostrate habit in the early stages of its growth, though said eventually to reach a height of 4 ft. to 5 ft. in Western Szechuan, where Mr. Wilson collected seeds in 1905. The bell-shaped pale rose blossoms seem almost too large and heavy for this delightful plant to carry. Mulched liberally with leaf-mould the growths spread and root freely in it. A. O.

NOTES OF THE WEEK

READERS are reminded that if they have not already sent their mowing machines for repair and overhaul, they should do so without delay. It is a great mistake to let the grass grow unduly long in spring before putting the machine on it, a bigger one still to "carry on" with a machine "out of tune." Another word of warning may not be out of place. It has reference to the abuse of the roller. Nothing so delights the soul of the handyman or jobbing gardener as to roll the lawn when the roller makes a "good" impression—otherwise when the sward is wet. The roller should only be used on turf when the surface of the soil is almost dry or what gardeners would call (in a border), in good working condition. Some readers will, no doubt, be contemplating the purchase of a new machine or new roller. In the case of the latter, a fairly light one should be selected. A heavy roller has no place on a lawn, although it may be useful for paths. That is where a ballast-roller comes in! With regard to lawn-mowers there is no excuse at present for anyone to buy a foreign machine. The cheapest effective machines on the market are British made, while if a *model de luxe* is wanted (to quote the motor

trade) British machines are far in front of the foreign ones.

The Toothwort *Lathræa clandestina*, is a parasite growing on the roots of the Willow, Poplar, Hazel and *Rhododendron*. It prefers moist, shady situations, where it spreads quickly, making large drifts or patches, where its lilac or bluish purple flowers provide a very pleasing note of colour in April. Mr. R. A. Malby writes, "At Warley place in Essex I have seen the very fine rich-coloured form here portrayed growing in thickly clustering masses down to the water's edge in association with *Iris*es and *Primulas*, and the contrast of its rich *Crocus vernus*-like colouring with outlying drifts of the naturalised *Narcissi* there so much in evidence, providing a peculiarly attractive colour combination. The flowering period usually lasts from mid-April to the end of June, while the growth appears in February in the form of a mass of white scales, amid which the flowers develop in dense clusters. This curious plant ripens seed plentifully, and upon the capsules attaining maturity they violently burst, throwing out the relatively large seed to a distance of 3 ft. Not infrequently the plant dies out only to come up again with vigour several yards distant."

LATHRÆA CLANDESTINA.

CORRESPONDENCE

PRIMULA WINTERI.

IT may be of interest to your readers to hear that since the last week in November I have had a constant succession of perfect blooms on one plant of *Primula Winteri* in my back garden on the north side of Edinburgh. The simple requirements of this exquisite Himalayan treasure seem to be a north-east aspect, a liberal supply of leaf mould and stones about its roots, and a small square of glass over its head during the winter months. At any rate, this treatment has with me resulted in a wealth of beautiful sea-green leaves covered with farina and a display of from four to twelve delicately scented, luminous, rosy lavender flowers at a time, over a period which will certainly extend to three months, if one may judge from the buds still unopened. I bought the plant last April and could wish no garden lover a more delightful experience than it has afforded. Later I hope to divide it and so increase the joy it has given me and others.—ANNE CHURCH, *Edinburgh*.

THE TENERIFFE BROOM.

AFTER the "Mimosa" there is no tree-like shrub more commonly seen in the Riviera battles of flowers, and flower fêtes generally, than the Tenerife Broom, *Genista monosperma*. Its feathery white sprays of blossom are so elegant and contrast so admirably with the Carnations and Anemones that make the bulk of decorations that it is quite an indispensable adjunct, and is therefore much grown for market purposes. Many folk probably, like myself, have heard the remark made first by one and then another that its scent is overpowering and yet again that it has no scent at all! Such an apparent anomaly needs a little explanation, I think, as *both statements are true!* Botanists can tell us whether this Broom is really dioecious or not, but any gardener can tell you there are two forms, one of which is very strongly scented and bears seed. The other has no scent and is quite barren. The barren or "male" form has smaller flowers, neater growths and *no scent*, so as it is earlier in flower than the fertile or "female" form, it is the most commonly grown for market. But for the garden the larger-flowered and strongly scented plant is decidedly the more ornamental and desirable, though its lanky growths require a little judicious pruning after the flowering season. It would be interesting to know if its habitat on the volcanic cinders of Mt. Tenerife has anything to do with this rather unusual peculiarity of habit or variation. There must be something unusual in a climate when the drought-loving Broom and the moisture-loving *Cineraria* grow so close together. Of course the *Cineraria* is only an annual, and therefore does not survive the summer heats, while the Broom is a long-lived shrub of very tough constitution on a well drained soil, only succumbing to the wet blanket of an English winter. As far as resistance to frost is concerned I have no doubt it would stand more than 10° of frost on a dry volcanic soil.—E. H. W., *Nice*.

THALICTRUM ADIANTIFOLIUM AND ITS HARDINESS.

IN your issue for January 27 you have a letter *re* protecting *Thalictrum minus adiantifolium* in the winter, and ask for other people's experience. It will interest you to know that at my old home we had a plant planted by my grandfather about fifty years ago. This was never protected in any way, and still survived the moist, foggy weather so prevalent at Oxford, and during that period must have experienced several very severe winters.

I have the same plant up here, within a few miles of the mouth of the Tees, and in spite of the position being extremely wet (almost waterlogged) and shaded from all sun except for about an hour in the height of summer, it survived last winter (1921-22), which was particularly trying, and is at present shewing signs of renewed activity. — M. ODLING, *Marton, Yorks*.

THE MYROBALAN PLUM.

I NOTICE so many remarks on the earliness of the present season that I send a photograph which I took of a Myrobalan Plum tree growing in a yard here on February 11, 1913, when it was in full bloom. At the time of writing the buds are well advanced, but none has opened nor is likely to do so for many days, even if the weather continues mild. The value of this beautiful early-flowering Plum seems to be overlooked by planters. Large specimens in hedgerows or outskirts of shrubberies are very fine in early spring, and in a favourable season will bear freely and the fruits are much esteemed for bottling. We have several trees here near to public roads, and they are always much admired in early spring.—H. C. WOOD, *Lingfield*.

CHIRYSANTHEMUM TOKIO.

I AM extremely sorry to have caused Mr. Harman Payne such perturbation and hasten to apologise. I thought quite innocently that he might have misread a label or made a slip of memory. In a longish life I have more than once made a mistake and have comforted myself with two proverbial sayings, one, "*humanum est errare*" the other, "the man who never made a mistake never made anything." But I see, of course, that Mr. Harman Payne would not make a mistake. —G. H. ENGLEHEART.

[This correspondence is now finished.—ED.]

PRIMULA CHIONANTHA.

I WAS greatly interested in the splendid illustration of *P. chionantha* in the issue of THE GARDEN of February 3, and note that seed of this beautiful species is being offered by Messrs. Barr and Sons, Covent Garden. This handsome species hails from Yunnan, where it was collected about ten years ago by G. Forrest. It is still rare in gardens, but deserves to be more widely cultivated. *P. chionantha* belongs to the *nivalis* section. The foliage is somewhat fleshy and coated with golden farina. The flower-stem rises to a height of 15 ins. or more and is crowned with many whorls of pure white flowers about 1 in. in diameter, which are sweetly scented. Its cultivation is not so easy as some people would

imagine and, like the majority of the *nivalis* group, it has the unfortunate habit of rotting off at the collar during the winter months. We must bear in mind that *P. chionantha* in its own native habitat is completely covered with dry

THE MYROBALAN PLUM ON FEBRUARY 11, 1913.

snow for about six months of the year, hence the reason why in this country it is difficult to keep this beautiful *Primula* in a healthy state during the winter when planted out of doors. This evil may be overcome to a certain extent by thorough drainage, planting on gently sloping ground and working in plenty of gritty soil at the time of planting; this will help considerably to ward off some of the excessive moisture during the dark, wet days of winter. In some parts it may even require to be protected overhead with glass. Unfortunately, *P. chionantha* appears to be monocarpic, but sets seeds freely, which should be sown immediately they are ripe.—W. SCOT.

THE SEASON.

THIS winter, so far, is the mildest I can remember. Throughout December and January we have had a large vase of Roses in the house, renewed every two or three days, and there are still a number in the garden. Roses of all sorts are still flowering, not only the Hybrid Perpetuals which often linger through December, but also *Wichuraiana* Dorothy Perkins and single Roses, such as Irish Elegance. The following list of flowers was made on the last day of 1922, and on January 31, practically all still remained in bloom, with the addition of Snowdrops, and what should be Crocuses, but, unfortunately, the sparrows are destroying them as soon as they shew colour. The scarlet-berried Elder was flowering; *Prunus pissardi*, in a sheltered place, shewed leaf with flower-buds on the point of

opened, and I had cut some branches of Japanese Willow (*Salix matubilis*) with catkins rim-long. The New Year's list:—*Veronica rupestris*, *Escallonia*, Double Daisy, *Polygala buxifolia*, *Hypericum* (small species and also Rose of Sharon), Miniature Marigold (*Calendula arvensis*), *Saxifraga Burseriana*, White Thrift, *Violas* (various), Common Primrose and also Double White, San Remo market Anemone, *Daphne Mezereum*, *Astrantia major*, Silver-striped Lamium, *Sisyrinchium striatum*, *Linaria Cymbalaria*, *Specularia Speculum*, Pink Mesembryanthemum, Alpine Strawberry, *Pulmonaria* (from Como), white Centaurea, yellow Wallflowers, Arbutus, Burnet, Periwinkles (*Vinca major* and *V. media*), Alyssum, Chamomile, blue Cornflowers (from the Somme battlefields), *Helianthemum*, *Schizostylis coccinea* (Kafir Lily), *Veronica salicifolia*, Zonal Geraniums (*Pelargoniums*), *Cyclamen* (from Como), *Aconites*, *Laurustinus*, Winter Jessamine, Pink Carnation, Red Hot Poker, blue Hepatica, Christmas Roses, Violets—and the following plants from Hyères: *Genista* species, *Bellis sylvestris*, *Dianthus* species, *Spiranthes*, *Allium triquetrum*—Roses of many sorts and a wild flower which happened to catch my eye, the common Buttercup, not a winter flowerer as a rule. There are far more flowers in our Yorkshire garden now than could be found at the same date last year at Hyères on the French Riviera, but three which might reasonably be expected are missing. There is not a flower (so far) on the Winter Honeysuckle, *Chimonanthus* or *Iris stylosa*. The latter, which did so well here last year, has doubtless suffered from the lack of sun in the summer, but it is curious that the summer which failed to ripen the roots for flowering should have served to ripen seed, which is already sprouting, sown in a pot in the open. A number of Orchises brought from Hyères last year are shewing flower-buds in the rock garden. —RUTH BICKERSTETH, *Coltingham*.

"SPOTTINESS" IN PLANTING.

"A PAINTER'S" note in THE GARDEN of February 10 in criticism of the illustration, "Admirably planned and planted," which appeared in the issue of January 27, will no doubt interest those of your readers who, like myself, are glad to know how a garden picture appears to a maker of pictures. "Spottiness" is certainly an undesirable feature in a garden, though it is a fault somewhat difficult to avoid where the space is small and a desire for variety clashes with a love of breadth and mass.

As regards the little picture in question, I cannot say that I find "A Painter's" remarks, though interesting, altogether convincing. It is a very cool and refreshing little scene and, very possibly, was "admirably planned and planted"; though, to me, it recommends itself as having been neither planned nor planted, but as having come into existence at the haphazard prompting of Nature. If it was "planned and planted," the aim of the planner and planter was, I should say, to conceal his art and plagiarise from Nature; and, judging from the illustration, though things are not always what the camera would have us believe, the planner and planter has been fairly successful. One has seen dozens of such woodland vignettes—a runlet of water, a few boulders, half a rood or so of turf more or less irregularly disposed and pied with Daisies, a clump or two of *Lastrea* and *Polypody*, a fringe of grasses at the brook-edge, a little bog of sedge, a pool with a few plants of Water Docks or *Alisma* and, hemming all in from the rest of the noisy universe, a boundary wall of foliage, Holly, it might be, or Alder. That seems to me to have been the rough pattern which the planner and planter had present to his mind when he made his little

Eden, bettering his instruction, no doubt, by introducing Funkias, Irises, Spruces and other fine plants which Nature does not introduce into her woodland scenes in this country, but which she uses lavishly enough elsewhere. Where I seem to join issue with "A Painter" is in the exception taken to individual plants in a garden picture of this kind as "unrelated" to their environment, that is, as having no business there. I quite agree that it is unpleasant to feel that a plant has no right to be where it is; but that it happens to be a single plant, say, of Funkia or Burdock, growing near other things on the bank of a stream does not necessarily mean that it spoils the picture. It may be the very thing wanted to emphasise something else, as, with deference, I venture to think the Funkia is in this picture. Isolated plants, as well as broad masses, have surely their picture value. It is often true with plants as with other things, that the part is greater than the whole. The characteristic beauty of a plant is often lost in the mass, as the beauty of an animal is lost in the pack or herd. To my thinking the Funkia in the picture has a finer effect than if the whole bank had been one mass of the plant. I quite recognise that "A Painter" is less concerned with the beauty of individual plants than with the part they play in the landscape. I would only say that, even as a feature of landscape, breadth and mass, though much, are not everything. Also I venture to think that, all regard being had to the value of mass, the illustration in question seems to present a scene too small in scale to admit of much massing. —SOMERS.

FOREIGN-GROWN PLANTS.

AS we hear that certain undesirable Dutch firms are again flooding this country with their gaily-got-up catalogues, we think the following letter which we received last summer from a customer may interest your readers: "I should like to thank you for the way in which you executed my small orders for rock plants last autumn. My garden is now full of colour, and I am more than satisfied. The plants came so well packed and grown that I do not think I have lost one.

I had some of the same kinds of plants at the same time from a Dutch firm, and though yours were certainly about double the price, they are ten times the value." The opinion expressed by our customer is by no means exceptional, and it is really where the Britisher scores every time over the Dutchman by giving his customers a better article and better service than he ever gets from Holland. For obvious reasons we should prefer that you do not publish our name, as we have no desire for a gratuitous advertisement. —LONDON SEEDSMAN.

[The foregoing letter might be so construed as to cast a slur on the general commercial morality of our industrious and patient friends the Dutch. We are sure such is not intended. There are, of course, Dutch nursery firms of repute, but it is not these who make such tempting offers to the unwary. The difficulty of reclaiming comparatively small sums of money once sent into a foreign country makes it easy for unscrupulous tricksters to exploit a not unnatural desire to buy in the cheapest market. —ED.]

A FINE PYRACANTH.

I AM sending you a spray of a remarkable Cotoneaster I obtained some few years ago as *C. angustifolia*. I never see it included in your otherwise interesting articles on Cotoneasters and am wondering why. Although it was some years before it blossomed or fruited with me, when once it "made up its mind" to fruit, it did it to some purpose. It is one of the most beautiful plants imaginable for the winter garden, as the fruits do not reach maturity until the end of the year. The berries are a very effective yellowish orange. Some of the sappy growth has been cut by frost on one or two occasions, but it stands out in the open here in Warwickshire. —C. L.

The plant in question is a Pyracanth, not a Cotoneaster. *Pyracantha angustifolia* has often been described in THE GARDEN. It is certainly valuable for its late-fruiting. Its berries often retain their beauty until March, but it is not, as a rule, very free to fruit. It was originally sent out as a Cotoneaster and is still listed as one in some nursery catalogues. —ED.]

A FRUITING SPRAY OF PYRACANTHA ANGUSTIFOLIA.

HERBACEOUS PHLOXES

WHETHER we use these gorgeous plants as "clumps" among other flowers or segregate them into a border that is "all their own," working this up from purest white at one end to the most intense hues at the centre, and paling off again at the most distant point to the softest of rose and heliotrope, it is certain we shall possess a rich store of colourful material from June to October.

They are, in short, among the best and most gorgeous of hardy border flowers and will grow

make superb specimens. In any case, it is a mistake to allow old plants to remain too long, for as they grow older they become harder and more woody at the centre year by year, with the stronger growths at the outside, until eventually the plant perishes. Big clumps, such as are seen in large gardens or in public parks, are not the result of old-established plants that have spread to a large size, but are composed of several small pieces put in close together. Every year, after growth has well started, a good mulch of leaf-mould or well rotted manure should be spread over the soil to a depth of 2 ins.

A BORDER OF PHLOXES.

grandly in practically any soil if a little trouble is taken with them. There are people who "cannot grow Phlox," and indeed their plants are a testimony to this, but I venture to be sure that is not the fault of the Phlox or the soil, but due solely to omission of that "little trouble" which makes all the difference between success and failure.

Deep trenching and liberal manuring are the first steps in every case and, whatever the nature of the soil, this must be regarded as absolutely essential. The kind of manure used must also be considered, in connexion with the quality of the soil. Upon a light and porous one, nothing is better than that from the cow; while a stiff clay is immensely improved by the addition of plenty of "long" horse manure and wood ashes. Anything, in fact, that tends to improve the texture of your particular soil should be employed, leaf-mould and shoddy being especially valuable. Happy is the man upon whom beneficent Nature has bestowed a rich greasy loam; he may grow Phlox to perfection, with "pips" of unparalleled size; for the rest of us it remains to get our soil as nearly to this as possible. Bear in mind that trenching has a splendid effect upon the drainage and mechanical condition of the ground, but also remember that the Phlox is a surface rooter, and manurial substances at a greater depth than 1 ft. to 15 ins. are wasted so far as they are concerned.

For the planting season, early spring is the best possible time and old clumps may then be split up or young plants from cuttings used. If your Phlox have failed to satisfy you I strongly commend a trial of the latter method, for the plants invariably

or gins. This is of great assistance in conserving moisture, a very important point with surface-rooting plants. Cuttings are very readily rooted in spring when a couple of inches of growth have been made, and a large stock of healthy plants can quickly be worked up in this way. Older clumps invariably make too many shoots and these, to secure fine heads, must be thinned. The shoots removed serve as cuttings.

Under a bell glass in a cool greenhouse is an excellent place to root the cuttings. Rooting, in sandy soil, is speedily accomplished. Directly they are ready the young plants should be transferred to single pots in a cold frame. Give them rich soil and grow them sturdily, and within a short time they will be strong enough to plant out in the border. Most of these will produce a head of flower the first autumn, though at a lesser height than they attain in subsequent years and are then good for three years without further propagation, though where a large number of kinds are grown, it is best to propagate a few new plants each season rather than deal with them in a wholesale manner at one operation, for then there will always be a good display in the finest possible condition. Summer watering is an important point and one must never allow the plants to become so dry that the foliage droops, or the best heads cannot be expected. Nor, on the other hand, should watering be done too often, especially if it is put on through a hose from the water main. This is too cold and chills the roots, but, in many cases, it is the only means by which watering can be done. In this case it is best to water only when really required and then in such quantity that the whole of the ground will be

absolutely soaked and so remain moist for several days.

Varieties are so numerous and so much inter-crossing has taken place between *PP. suffruticosa*, *maculata*, *pyramidalis* and *paniculata*, that the original distinctions have almost disappeared and, by consulting a list of a specialist in these grand hardy border flowers, practically any colour and height can be obtained with different varieties flowering from June to October. Some of the newer varieties, however, have lost in size and shape of truss what they have gained in size of pip. For garden decoration the form and size of the truss is, next to the colour, the most important item of all.

H. W. CANNING-WRIGHT.

FRUIT TREE STOCKS

NOT a great many amateur gardeners, even of considerable skill, realise that fruit trees may be fitted into different sized spaces. The size to which fruit trees attain when full grown depends partly upon soil and partly upon position, but mostly upon the kind of stock on which the trees were budded before being sent from the nursery. This fact will be taken advantage of by those who wish to plant a fruit tree in a space of a certain size, or where more than one tree is to be planted in a limited area.

After a careful study of the growing capacity of different stocks—and this capacity gives a wide range of choice—it should be fairly easy to get a tree suitable for almost any position. Naturally, the shape of the tree will also make a difference to its suitability: whether bush, pyramid, standard or half standard; for the purpose of this article we may leave cordons alone.

The shape of the tree, however, also depends upon the stock: it is hopeless to attempt to obtain a standard from a tree grown on some of the weaker stocks, and it is just as hopeless to attempt to confine a tree on strong-growing stock to bush or quarter standard size.

Perhaps a few general hints as to the right stock for large or small-growing trees may not be out of place, but it should be remembered that there are a few kinds of Apples which will not flourish on every kind of stock. The choice, however, is far from limited and plenty of scope is allowed, Apple trees that are required to grow to large size should be on crab stock, while those required to grow only to a comparatively small size would be best on English broad-leaf paradise. In between these there are other kinds of paradise stocks that will serve the purpose.

Pears to grow to large size will need to be on pear stock, but no crop of Pears need be expected on trees on this stock for the first few years after planting. There is still a lot of truth in the old couplet, where pear stock is used—

"He who plants pears,
Plants for his heirs."

Pear trees to grow to smaller size should be on quince stock,

It ought, perhaps, to be mentioned that Apples on paradise stock will begin to bear fruit a few years before Apples on crab stock, but the difference is not nearly as great as in the case of Pears. Another point to be borne in mind before finally deciding as to the choice of stock is to remember that Apples on paradise stock are rather more liable to canker than Apples on crab stock, but in either case, if properly looked after, they will live and flourish for a good many years.

J. W. MORTON.

THE OLD ENGLISH HERBALS

THE Old English Herbals," by Eleanor Sinclair Rohde, is a book which is full of interest to all who include or who wish to include the ancient connexion between plants and diseases in their pharmacopæia of knowledge, doctors especially. To quote from William Clowes' introductory poem in Lyte's Herbal, if the reader will substitute lady for gentleman,

"And sure I am all English hartes that lyke of
Physikes lore

Will also lyke this gentleman: and thanke
hym muche therefore."

Gardeners, too, will like it. The history of plants is ignored by many, but this omission, I venture to think, is only because the past is a sealed book. Our authoress has opened one of the sealed chambers of that past in all she has told us about the manuscript herbals of our distant forefathers, and I am only sorry she does not make it clear that much of her knowledge has been extracted from a somewhat rare work, "Leechdoms, Wort-cunning and Starcraft of early England . . ." collected and edited by Oswald Cockayne in three royal 8vo volumes, 1864-66. It is an official publication of the Record Office, and from its size it is needless to say that Miss Rohde—although she has been a wonderfully busy bee—has not extracted all the honey. From manuscript she passes on to printed herbals, stopping short in her quaint extracts with Culpeper, whom one might almost describe as a super-popular quack, and Coles the lawyer exponent of the famous Doctrine of Signatures. It is a pity, for the book is good reading. Macer's Herbal, Turner's Herbal, Gerard's Herbal, Parkinson's Herbal and his Paradise, with many more, are dealt with, and as a sort of Grangerised addition a good many pages are given to "Sixteenth and Seventeenth-century Still-room Books." They are near akin to herbals; they have a good deal in common with books on cookery and just a little with the "vandy" bags of the twentieth century. "Bales for the face" and "Divers excellent sentes for Gloves" come under this category. This last heading is from a similar book by Sir Hugh Platt (c. 1630), which is not mentioned by our authoress, but which breathes the same spirit as Lady Sedley's Receipt book and the Still-room book of Sir Kenelm Digby. Platt's "Epistle" at the commencement of this book, "Delights for Ladies," is very quaint and shews him to have been a lady's man:

"Rosewater is the ink I write with all.

Of sweets, the sweetest I will now commend,

To sweetest creatures that the earth doth beare:

These are the Saints to whom I sacrifice,

Preserves and conserves both of plum and peare."

It is very hard to know where to stop and very hard to know what to put in and what to leave out in writing in the enthusiastic way that Miss Rohde does. But if ever a second edition is called for, might I suggest that more might be said about Dr. Agnes Arber's "Herbals." One book throws light upon the other.

Then in one or two cases references might be given to, or at any rate the name mentioned, of the book that has been used in the text. For example, if I mistake not, in dealing with the Vegetable Lamb (pages 143-5), Miss Rohde has had access to Henry Lee's "The Vegetable Lamb of Tartary," which might be called the chief stone-house of information on this very absorbing subject. There are a few slips in the text, as

for example on page 9, Sunflowers are said to have been grown in Saxon gardens; the date of "A little Herbal" printed by John King (page 200) is given as 1550, when King did not begin to print until 1555; and on page 195 an "e" has changed places with a "t" in describing

the town in which John Lelamour, a schoolmaster of Hertford, lived.

These little matters do not affect the general interest of a book which one feels has been, as the authoress claims in her preface, "a labour of love."

JOSEPH JACOB.

SEMI-NATURAL GARDENING

WE cannot help a feeling of sadness when we see the owners of our grand old establishments trying to keep up appearances with a much reduced income. Only the other day I heard of one of these cases which almost brought tears to my eyes. Not very long ago there was an elaborate, well kept formal flower garden situated close to the mansion in a noble park. The flower-beds are still there, but they are furnished in a different and not an improved style. Now, I think, in many cases where the limited income will not allow such beds to be furnished properly it would be much better to do without them and revert to a more natural style. I have no great love for masses of scarlet Geraniums and yellow Calceolarias anywhere, and when these have to be replaced by ephemeral annuals the effect is still more jarring on one's taste.

A greensward with hardy flowering plants and shrubs placed in suitable positions would certainly not have such a poverty-stricken appearance. There are many beautiful things in this way which will almost take care of themselves and, indeed, excepting in a formal terraced garden, which is partly architectural, I prefer them to formal beds. But they require an artist to arrange them. Pampas Grass, Tritomas, umbrella-trained Rambler Roses, Yuccas, Aralias and Bocconias are among those which occur to me at the moment, and there are many others, but it is well not to have too many. Among shrubs is *Pyrus japonica*, which makes a handsome bush, sometimes 2yds. or 3yds. in diameter. The silver-leaved *Picea Nordmanniana* is handsome as a small tree, and various *Barberies* are suitable; but not stiff-growing Irish Yews or the columnar Cypress. If the lawn is a large one, it may be permissible to have a bed or two of *Kalmias*, *Rhododendrons*, *Mahonias* and the like, planted thinly and carpeted with *Snowdrops*, *Daffodils*, *Crocuses*, etc.

Where there is anything like a shrubbery it may be made attractive by taking out some of the shrubs at irregular intervals and different areas and introducing hardy flowering plants. It is best not to have a long, straight line of turf or gravel, but there must always be a visible excuse for the deviation; something must be in the way to shew why the bend is there. We must not imitate the professional who made serpentine walks among the Cabbages. Where there is a woodland walk, or rather a walk on the outskirts of a wood with an irregular breadth of turf between the two there is scope for much tasteful arrangement. I remember our veteran friend and tutor, Mr. William Robinson, coming across a batch of summer *Snowflake* on the grass backed up by the green leaves of *Rhododendron ponticum*, being so delighted that he went down on one knee to it. I passed this spot daily, and if there was a leaf of the shrub in the way it was picked, but no one could see there had been any manipulation. I believe this was figured in "The Wild Garden," but I have never seen that work. Another patch was the Evening Primrose growing out of the grass and backed by shrubs which the artist Alfred Parsons thought good enough to make a drawing of.

These things happened nearly half a century ago, when I wrote the following, which, I think, is better than I could do it now, but then I was close to Heaven's Gate, the hallowed spot where the saintly Bishop Ken composed the beautiful morning hymn, "Awake my soul." Such associations ought to touch the most barbarian mind.

"One of the most enjoyable places on earth is half wood, half shrubbery, carpeted with low-growing plants, producing a succession of flowers throughout the four seasons, and with a well drained walk, not too trimly kept, but such as can be used in all weathers, where there are gigantic trees to shelter from sun and rain, and rustic seats at intervals on which to rest while listening to the music of the birds and inhaling the odours of the flowers. If ever I make a spring garden in accordance with my own ideas, it will be in such a spot as this. Aye, and my summer, autumn and winter garden shall be there too, for I will have a perpetual succession of flowers from the Winter Aconite to the Christmas Rose, not in ribbon borders and carpet patterns, but in humble imitation of Nature's own sweet ways. . . . The greatest art lies in concealing art. If I am asked concerning a plant or a mass of plants which has only been in position year or two, 'Did you plant that, or was it always there?' I feel it is the greatest compliment I can receive."

But when I try competition with Nature I am frequently second best. Those glorious masses of Grape Hyacinths, Primroses, Foxgloves, etc., stretching away under the boughs of the Hazel and losing themselves in the distance are better by far than my puny attempts at decoration. The Winter Heliotrope growing on a shaded clay bank, where no other flower can exist, filling the air with its fragrance during the shivery season, seems to be thriving in perfect luxury. The larger Periwinkles will overrun most weeds and kill them in time, and the common St. John's Wort has taken possession of a partly shaded bank where, when not shewing its elegant blossoms, it is a mass of emerald green. Honeysuckles and wild Roses have a charm of their own, but some of the Penzance Briars and single Ramblers might be introduced, as well as a Clematis or two, especially montana.

Bulbs, too, would make a pleasant feature and might include *Snowdrops*, *Daffodils*, *Lilies* and *Jonquils*. Where turf is growing between the shrubs and the walk it should not be cut to a line next the shrubs, but should lose itself under them. I have a great objection to trimming shrubs too formally, as is frequently done in our public parks. Some trimming is necessary, but the marks of the workman should not be visible.

If this style of gardening is taken up by ladies and gentlemen who have some leisure and good taste but who cannot afford a more expensive method of decoration, they will soon find it will relieve them of many a tedious half hour, especially if they will condescend to do a little of the work themselves. Garden labourers generally are not adepts in this kind of work. They want to do too much, and they leave their marks behind them.

WM TAYLOR.

NOTES ON FREESIAS

"DUDS."—I fear the flowering season of 1923 has not been quite up to that of 1922, on account of the numerous "duds" that have appeared in many collections. I am told that this lying dormant for a whole year is a characteristic of several South African bulbs. It certainly is of the Freesia, and sad experience now makes me include the white Freesia. Until this year I did think that the whites were immune, but I can at the moment of writing shew anyone a whole pot of "Purity" in which every bulb is a shirker. We live and learn. It would seem that this tendency to remain immovable in the ground is "the fault and corruption of the Nature of every" Freesia that is born into the world, and that it only requires suitable conditions for this tendency to show itself. Those conditions were present in 1922, inasmuch as the summer of that year was cold and sunless, and the early autumn no better. After the almost tropical summer of 1921, I could

here, one with variegated foliage. There seems to be an albino taint in the family, for pure whites often appear in our seed pots, but they have only short butterfly existence and long before the time comes for their green brethren to die down they have disappeared. There was no sign of this variegation in the seed pots, for my gardener and myself keep far too watchful an eye on them to have missed such a novel breakaway. Something must have happened during its first resting period, the result being that there is a healthy normal looking plant with all green foliage replaced by white and green. It is going to flower in quite the usual way. One never knows, my one ewe lamb may not be the uncommon creature that I think it is. Again, what is the experience of others?

OPEN OR CUP-SHAPED?—Apothéose is by many considered to be the high water mark of coloured Freesias. I have grown several potfuls for the first time and I can unhesitatingly say that it is a fine

YELLOW FREESIA CANARY WHICH IN 1919 MR. JACOB DESCRIBED AS FREE FROM "DUDS"

count our "duds" on the fingers of my two hands. Seeing is believing, otherwise I could never have realised the difference a warm and sunny and a cold and sunless ripening season can make. The practical question for those who grow Freesias—more especially the coloured varieties—is "can anything be done to help matters when Nature is unkindly?" I am experimenting. One year's experience suggests that if the bulbs are kept nice and warm *both before and after* they are planted, this trouble will be overcome. Don't you know how uncongenial company and surroundings freeze one up? Pity then the poor Freesia when it is in similar circumstances, and do not blame the dealer who may have sent you more "duds" than you wanted. To the true gardener exchange of experiences is like charity. It blesses both the writer and the reader. Here you have mine—now won't others tell us theirs?

A NEW COMER.—I have grown coloured Freesias for many years. I had my first from Van Tulergen of Haarlem almost as soon as they were put on the market, but never until this year have I had among all the hundreds of seedlings that have been raised

thing. Tall in stature, strong in limb and pleasing in face (flower), but this grand flower lacks one supreme characteristic in my judgment. I do like a bloom where all the segments open out flat and in tulip language, "quarter." They are so much more graceful either considered from the pot plant point of view or from the vase standpoint. I know why this loose type of flower will never become very popular. Market men will be against it. It won't pack. I allow this, but it is no reason why private growers who grow for their own pleasure should not go in for them. They would then have something that could not be bought in the ordinary way in shops.

JOSEPH JACOB.

FORTHCOMING EVENTS.

March 5.—Lecture at the University College, Gower Street, London, W.C.1, at 5 p.m., by Dr. A. D. Imms, on "The Invertebrate Fauna of the Soil (other than Protozoa)."

March 6.—Royal Caledonian Horticultural Society's Meeting.

March 7.—Lewes Horticultural Society's Meeting.

Lecture at the University College, W.C.1, at 5 p.m., by Sir John Russell, F.R.S., on "The Chemical Activities of the Soil Population and Their Relation to the Growing Plant."

EARLY VEGETABLE BORDER

IF the weather is favourable and the soil in good condition for working a sowing of the following vegetables may be made forthwith. A well drained sheltered site (preferably a south border) should be selected for this purpose. Large sowings are not advisable at this early date.

Peas.—Early dwarf varieties should be sown in broad drills 2 inches deep. A sprinkling of soot over the seed before the latter is covered with soil is beneficial. On very heavy land the seed should be covered with old potting soil, or a special mixture of leaf-mould and loam. Narrow borders can be sown without the necessity of much treading upon the soil. The seed should be sown fairly thick for these early crops. Allowance must be made for rot or destruction by pests below or above ground. As soon as the young plants are visible, protect them by drawing up a little soil on each side of the rows and place pea-guards over them.

Spinach.—A small sowing of this excellent vegetable will provide a supply at a time when it is much appreciated. Seed should be sown in shallow drills 1 foot apart. Cover lightly and dust the surface of the bed with soot. Sparrows will quickly destroy the young crop unless precautions are taken to keep them off by the use of nets, pea-guards, or strands of black thread.

Carrot.—Early Short Horn Carrots delight in a warm, light soil. A slight covering of wood-ash may be raked into the bed before preparing the drills.

Turnip.—A very quick-growing Turnip, such as Early Milan, is very useful. As these are liable to "bolt," only a small sowing should be made. Protect the bed from birds.

Cauliflower and Cabbage.—Sow thinly seed of an early variety of Cauliflower. Prick out the seedlings as soon as they can be handled, finally planting out on rich firm land. Early Cabbage raised now will form a succession to the autumn-sown crop.

Broad Beans.—In many gardens this is the first crop sown in the open ground. For the early border Beck's Dwarf Broad Bean can be highly recommended.

Lettuce.—An early Cabbage Lettuce, such as Commodore Nutt, which only requires a space of from 4 inches to 6 inches from plant to plant, is very hardy, of good flavour, and is always appreciated.

Radish.—Sow one of the small-topped varieties, such as Early Rose. Radish crops often fail owing to the seed being sown much too thickly and neglect of thinning the young plants.

Parsley.—Plants raised from this sowing will provide a good supply during the summer. Parsley seedlings should be planted out from 9 inches to 12 inches apart according to the variety grown.

Potatoes.—In very sheltered gardens in the Southern Counties a few early Potatoes can be planted, especially where adequate means are at hand for the protection of the crop when the haulm appears above ground. Potatoes can be planted in a ridge of light soil at the foot of a south wall. In this position they obtain the full benefit from the sun during the day, and can easily be protected at night. COLIN ROSE.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Onions. Autumn-sown Onions may be transplanted about a foot apart, but their keeping qualities only warrant the planting of a few lines just to supply the kitchen until the spring sown crop is ready. Seeds for the main crop should be sown at the earliest opportunity, because to get really fine bulbs a long season of growth is essential. Make the ground firm by treading or rolling, and after raking the soil to obtain a fine tilth, shallow drills should be drawn 10 ins. apart. Sow the seeds thinly, and when the drills have been filled in with the foot, rake the bed, thus giving the whole a neat appearance. On light soils the roller may be employed again after the seed is sown. Good kinds of Onion include Ailsa Craig, Cranston's Excelsior and James' Long Keeping.

Potatoes.—Tubers that were set up in boxes as advised some time ago, have formed strong short-jointed shoots and should now be planted on a warm border. Deep drills should be drawn or chopped out with a spade about 2 ft. apart and the tubers placed at intervals of 18 ins. Care is necessary when covering the tubers to prevent injury to the growths. A sprinkling of ashes from the rubbish fire may be given. The seed tubers for the main crop should be examined at intervals and placed thinly in a cool shed where the shoots will remain dwarf.

Lettuce.—Plants raised in boxes will soon be large enough for pricking off. A few boxes may be used for this purpose, setting out the seedlings a few inches apart and growing them on in a warm greenhouse. The remainder of the plants can be transferred to a cold frame, dusting the soil with soot to keep off slugs.

The Flower Garden.

Pruning.—*Buddleia variabilis* and its several varieties should now be pruned, cutting the growths back that flowered last year to two or three eyes. A few weeks hence the new shoots may be thinned, removing any weak ones and leaving the strong, which will produce fine sprays of flowers in due season. *Hydrangea paniculata* may be cut down near to ground level, and the same remark applies to *Panownia imperialis*. Ivy growing on walls may be clipped close to the stems, and if such work is carried out now the plants will only be bare for a short time. *Ceanothus* of the Gloire de Versailles type ought also to be cut back, but *C. dentatus* must not be pruned at this season.

Lawns should be rolled occasionally to keep down worm-casts, thereby preparing the lawn for the mower in the near future. If not already done, the mowing machines should be put in order at once. A dressing of sulphate of ammonia will destroy any moss that may be present on the lawns and at the same time strengthen the grass. One pound to a pole or perch will suffice and, unlike several other artificial, it discourages the growth of clovers and encourages the finer Grasses.

Gladioli. The many beautiful forms of Gladioli constitute a wonderful race of late summer and autumn flowering plants, and they deserve to be planted in quantity. A border should be devoted to them, but clumps in other parts of the garden will also prove effective.

Sweet Peas. Seed may be sown in lines 6 ft. apart or in clumps in the borders. A rich soil is essential, and this is usually prepared in the autumn.

Fruit Under Glass.

Melons. Seeds ought now to be sown for the general or main crop. The earlier sown plants will need tying to the wires and will soon be approaching the flowering stage. When four or five female flowers are open at one time they should be fertilised with pollen from the male blooms. At this stage the atmosphere should be on the dry side, but the roots must be kept well supplied with moisture. Four or five fruits are enough for one plant, and it is necessary for them to be set at the same time, because if one fruit is allowed to swell it is a difficult matter to get other fruits to form. A top-dressing of fibrous loam should be given, and the lateral growths will need pinching at the third leaf, the object being to maintain sufficient shoots to cover the trellis-work or wires and to encourage the flow of sap. Overcrowding must be guarded against, and to this end it may be necessary to remove a few laterals later on. When the fruits are set the atmosphere should be kept moist,

and air admitted in the forenoon when the weather is favourable. Maintain a night temperature of 65° and net the fruits when they are about the size of a hen's egg.

F. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.,
Castleford, Clepton, Gloucestershire.)

FOR NORTHERN GARDENS.

The Kitchen Garden.

Peas. Taking it for granted that a sowing of a first early variety was made about a fortnight ago, a sowing of a second early variety, such as Senator or Royal Salute, should now be made. At this early season it is still advisable to damp the seeds and roll them in dry red lead to ward off the attacks of rats and mice.

Broad Beans.—Make a good sowing of a long-pod variety, Bunyard's Exhibition and Seville Longpod are both good. Sow in rows 2 ft. apart and allow 6 ins. between the seeds in the row. Red-lead the seeds previous to sowing.

Spinach.—Make a sowing between the rows of the first and second sowings of Peas. Run the Dutch hoe through between the lines of the autumn-sown batch. Make a sowing in heat of the New Zealand Spinach. This crop if planted on a warm border at the beginning of June comes in handy when the ordinary Spinach runs hopelessly to seed.

Onions.—Spring sowing in the open is not much to be recommended, as the condition of the resultant plants just suits the taste of the Onion fly. Those who mean to follow this system for any reason should get the seed in without delay. The ground having been recently dug or forked over, should be raked smooth and trodden firm. Shallow drills should then be drawn at 18 ins. apart, and the seed having been sown thinly, should be covered by means of the rake. It is, of course, understood that the operation cannot be undertaken if the soil is in a wet, pasty condition. James' Long Keeping and Strasburg are two suitable varieties for sowing at the present time.

Parsley.—As the seed takes six weeks to germinate, the sooner a good sowing is made the better. In gardens where the "fly" is troublesome success can generally be achieved by sowing alongside Box edging at about a distance of a foot from it. Extra Triple-curved, if true to name, is hard to beat.

Celery.—Sow for the main crop in shallow boxes filled with light, rich soil in a temperature of about 60°. Wright's Grove Pink and Grove White are excellent varieties.

The Flower Garden.

Sweet Peas.—Where seed was sown in a cool greenhouse about a month ago the resultant seedlings should now be transferred to a cold frame, keeping the latter rather close for the first week. Those who had no accommodation for sowing under glass should sow now where the plants are to flower. Roll the seeds after damping them in dry red lead. Sow in shallow drills, placing the seeds about 2 ins. apart.

Dahlias.—Pot up cuttings into 3 in. pots and retain in a warm house until April.

Half-Hardy Annuals.—It is a trifle early to sow the bulk of these, but Sweet Scabious and Asters should be sown now in moderate heat.

Cuttings of Heliotrope, Lobelia, etc., should be pricked off or potted as they become rooted. Insert more cuttings if necessary.

CHARLES COMFORT
(Formerly Head-gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Erythrina Crista-galli. Large specimens of this handsome plant are very useful for conservatory decoration. Where they have been stored away dry for the winter they may now be removed to a greenhouse and given a good soaking of water at the roots. An inch or 2 ins. of the old soil should be removed from the surface of the pots or tubs, replacing it with a good rich compost. If it is desired to increase the stock of plants, it can easily be done by means of cuttings when the young shoots are about 3 ins. in length. These root readily in a case with slight bottom-heat. This plant is also easily propagated by means of

seed. Until they make a woody root-stock the young plants should not be dried off too much for several winters. This plant only requires cool greenhouse treatment during all stages of its cultivation.

Begonia Gloire de Lorraine and its varieties should be propagated according to requirements and as suitable cuttings are available. Young shoots springing from the base of the old plants should be selected for cuttings, and are best inserted singly in thumb pots, afterwards plunging them in a warm propagating case. A late-rooted batch of plants grown in sixty-sized pots is very useful for table-decoration. The American variety Mrs. Petersen has dark-coloured foliage which shows up well under artificial light. It is much slower growing than the ordinary type, and the plants are really at their best in their second year. All the Lorraine type of Begonia enjoy a light rich compost.

Begonia semperflorens gigantea rosea.—It is surprising that this fine Begonia is not more generally grown for furnishing the greenhouse and conservatory, for by growing successional batches it may be had in flower more or less all the year round. It is easily propagated by means of cuttings, grows freely in an intermediate temperature of 50° to 55°, and, when in flower, stands for a long time in an ordinary greenhouse.

Abutilon insigne is an ideal plant for planting out in a conservatory and training on a rafter under the roof. If it never flowered it would still be worth growing for its large, dark green leaves. During winter and spring it produces its red, dark-veined flowers in wonderful profusion on long, slender, cord-like shoots. It is easily propagated by means of cuttings, and when planted out grows very quickly. After flowering it should be thinned out, retaining the young shoots for growing on. Abutilons generally are not much grown at present. Still, some of them, such as Golden Fleece, Boule de Neige and Firefly, are excellent for planting out in large conservatories, especially for covering walls. They are somewhat dense for the roof, and require to be kept well thinned out. Abutilon vexillarium and its variegated form are slender-growing plants well adapted for furnishing wires or rafters, as also is A. Milleri, a hybrid of the above species. They are all easily propagated by means of cuttings.

Achimenes in many varieties are very useful and beautiful for furnishing the greenhouse during the summer months. The scaly rhizomes which have been stored dry all winter should now be started in a warm house, laying them in leaf-soil and sand in shallow boxes. When they have made growth some 3 ins. in length they should be transferred to pots or pans. Fine specimens may be grown in large, shallow pans, especially such strong-growing species as A. longiflora and its varieties. Some of the smaller-growing sorts will do well in 48-sized pots, while some of the more slender-growing varieties are excellent for baskets. These plants enjoy a well drained, light, rich compost, and should be grown in a temperature of 55° to 60°, giving them cooler treatment as they come into flower. They are very subject to attack by the Begonia mite, which, however, is easily prevented by the occasional use of the sulphur vaporiser. In recent years they have suffered very much from attacks of white fly. Fumigating with sodium cyanide is the best cure and preventive, but as great care is required in the use of this extremely poisonous substance, many cultivators prefer to use one of the proprietary articles offered for the purpose.

SPIRÆA PALMATA AND OTHERS

IF I were doomed to grow but one herbaceous Spiræa, my choice would lean towards that superb species named above, and few would question the assertion that this is one of the finest plants ever introduced to British gardens.

S. palmata varies very widely in stature and the colour of the flowers, but the typical form is some 3ft. in height, the broad-leaved foliage, drooping from the many-branched growths, being not less handsome than that of *gigantea*, to which it bears a close resemblance. Above this elegant mass of green, rise the flower-heads, these consisting of large, somewhat flat plumes of a vivid rosy red in which there is just enough chalkiness to soften the hue without dulling its brilliance.

From plants in this colour one may see *S. palmata* in a variety of intermediate shades, to white, but the real *S. palmata alba* is no half-hearted affair. It is one of the whitest of its race, without a hint of blush or any other colour to mar its spotless purity. Though all forms of this species are suitable for semi-shade, I do not think *S. p. alba* ever looks so well as it does under trees, especially where it can be associated with Ferns and other native herbage of moist woods. A grouping of this variety in such a situation appeals to one as the very acme of quality and good taste.

Nurserymen now list several forms of *S. palmata*, other than the above, and few of these are unworthy. The typical plant, however, looks best alone, in company with the pure white, or worked in with some other species which will not detract from its peculiar loveliness. On the other hand, there are forms of *S. palmata* which, since they differ only from the typical species in stature, may be accorded similar treatment and not less respect. Some of these being no more than 18ins. in height, yet bearing flower-heads as large and as richly coloured as full-sized specimens, are very useful where space is a consideration.

From these intermediate forms we descend to the diminutive *S. digitata*, which appears to be none other than a very dwarfed counterpart of *S. palmata*, with all the latter's brilliance of colour and an added touch of ruddy bronze in the foliage. What, exactly, *S. digitata* is perhaps no one knows, but most authorities believe it to be as stated. One thing, however, it certainly is not. I refer to the half-sized *palmatas* already mentioned and which sometimes bear the name of *digitata*. The true *S. digitata* is no more than 4ins. to 5ins. in height when growing in average soil, but it will aspire to rather greater dimensions where the living is especially to its liking. In any event it is a most charming little thing, easily pleased in any cool site and quite permanent and hardy.

S. lobata (*venusta*) is also not infrequently sent out labelled *digitata*, but the former is some 18ins. to 24ins. in height. Its flowers are even brighter in colour than those of *palmata*, and to my eye their dazzling carmine contains just that touch of hardness in tone the absence of which seems to afford those of *S. palmata* their peculiar and distinctive loveliness. A. F. J.

A Fragrant Warm House Plant.—That sweetly scented plant, *Mitrostigma ascellare*, is a native of Natal and although not likely to succeed in a cool greenhouse, it is well worth growing by anyone who has a warm greenhouse. It makes neat plants in pots, but perhaps is seen at its best when

planted out in a well drained bed or border. It produces its fragrant white flowers very freely during winter and early spring. It is easily propagated by means of cuttings, which should be placed in a warm propagating case. This plant grows well in a compost of good medium loam, with the addition of a little peat or leaf-soil and sand. In its younger stages it should be grown fairly warm. It will stand in a low temperature when in flower.

Two Valuable Musks for the Greenhouse.—*Mimulus glutinosus* (syn. *Diplacus glutinosus*) is an old garden plant, which is by no means generally cultivated at the present day. The species has rather small yellow flowers and is by no means common, its place being taken by a larger flowered variety known as *Sunbeam*, and the variety *coccineus* or *puniceus*. They are all easily propagated by means of cuttings made from young soft shoots, which root readily in a slightly heated case. They grow quickly in a cool greenhouse and are rather subject to attacks of green fly which, however, are easily prevented by occasional fumigations. *M. Harrisonii* is a large-flowered form of *M. moschatus*, which at one time was very largely grown in pots for the conservatory, as well as for planting outdoors during the summer months. It is, however, seldom seen at the present day, which is a pity, as it is a pretty and useful plant and its cultivation presents no more difficulty than the ordinary Musk. The latter for some unexplained reason has now lost its scent, and if any reader has or knows of a plant (or plants) with the old-time fragrance we should be pleased to hear from them.

A Neat Dwarf Shrub.—*Polygala Chamaebuxus* is an interesting plant suitable for the rock garden, forming a compact evergreen tuft with cream-coloured flowers which are borne in profusion. The variety *purpurea*, however, is a great improvement on the type. It is a neat little shrub some 4ins. or 5ins. high, with dark green box-like leaves and purple flowers with a yellow centre. Owing to the mild and open weather it has been more or less in flower since Christmas, and in mid-February the small plants of the variety *purpurea* were covered with blooms. A native of Central Europe, it should be planted in a cool, well drained position, such as near a large boulder, with peaty soil as a rooting medium. Soil which will grow Heaths or Rhododendrons will suit the *Polygala*. These plants are quite hardy, and they can be increased by division. Young growths are often available at the base of the plants, and if these are removed with a few roots attached they readily form nice little shrubs capable of taking care of themselves on the rock garden. On account of their flowering during the winter months they should be well represented in every garden.

About Hop Manure.—The Editor has lately received several enquiries as to the efficacy of hop manure as a fertiliser. This is an old and proven manure which, years ago, he used by the boatload not only for gardening but for agricultural purposes. It never disappointed, and in dry seasons was invaluable. The proprietary article marketed by Messrs. Wakeley is drier and more pleasant to handle than the crude product from the brewery, also it appears more concentrated. There is no doubt that this is absolutely the best and cheapest substitute for stable manure, which it replaces in every way. If everyone who cannot get stable manure used hop manure there would be a shortage, but obviously they do not!

Fish Manure.—We have received from the Humber Fishing and Fish Manure Company, Limited, of Hull a copy of a very interesting letter recently received from the Principal of the Leyton-

stone Council School setting out details of experiments made by the scholars with the Company's "Eclipse" Compound Fish Manure. Special reference is made to wonderful crops of Potatoes and Onions, and the schoolmaster gives it as his opinion that the boys who are going out into the world to earn their own living will be walking advertisements for this special manure. The Humber Fish Manure Company will be glad to send a copy of this unsolicited testimonial to any reader who is interested, and in addition will send full particulars of the manure referred to. That this is a very good and reasonably priced manure the Editor knows from personal experience. It gives especially good results for root crops and for Chrysanthemums.

ANSWERS TO CORRESPONDENTS

THE GREENHOUSE.

SCHIZANTHUS UNSATISFACTORY (A. Regular Reader).—The *Schizanthus* has been kept rather too warm at some time. Kept in well ventilated conditions, properly watered, and at not too high a temperature for the available light, the plants should recover before long.

TREATMENT OF PALM (A. G. S.).—Palms should not be over-potted and as our correspondent's specimen is of good colour there is not much wrong with it. A weak stimulant occasionally is beneficial. A weak liquid made from cow manure and used in a clear state, applying one dose each month during the summer and a teaspoonful of sulphate of ammonia dissolved in half a gallon of water and applied in June would help the growth of the fronds. The soil must always be maintained in a medium state of moisture, neither too wet nor too dry. Also, the plant should be taken outside once fortnightly and receive a good syringing. There would not be any need, then, to place the Palm in a nursery.

FRUIT GARDEN.

RASPBERRY LLOYD GEORGE (W. B., Hants.).—This variety is claimed to be perpetual-fruiting, that is, throughout the summer and autumn months. The fruit is borne on the young growths and also on the laterals, the latter bear the later or autumn crops. Our correspondent has done quite right in cutting down the old canes planted last autumn.

MISCELLANEOUS.

PLANTS SUITABLE FOR PAVING (E. E. B.).—The following kinds of plants will be suitable in addition to the Saxifrages, Dianthus and Thyme: *Acena microphylla*, *Ajuga reptans*, *Antennaria tomentosa*, *Arabis*, *Aubretia*, *Sedums* and *Sempervivums*. The following are annuals, and should be raised from seeds sown in boxes and duly transplanted: *Leptosiphon androsaceus*, *L. aureus*, *L. roseus*, *Saponaria calabrica*, *S. alba* and *Mesembryanthemum tricolor* in various colours.

NAMES OF PLANTS.—R. H. B., Cornwall.—1, *Azara microphylla*; 2, *Phillyrea decora*; 3, *Prunus lusitanica*; 4, *Buxus sempervirens*; 5, *Olearia Ilastris*; 6, *Berberis Aquifolium*; 7, *Skimmia japonica*; 8, *Taxus baccata*.—"Wimbledon."—*Helleborus corsicus* (*argutifolius*).—M. E. B., Wootton.—*Crassula lycopodioides*. This plant is a native of South Africa, and would not live outside in the rock garden in this country.—S. P. R., Cardiff.—*Crocus Balansea*.

NAME OF FRUIT.—T. A. P.—Apple Newton Wonder.

A Profitable Currant.

MERRYWEATHER'S 'SOUTHWELL RED'

For SPRING PLANTING.

Fruit growers should not miss planting this excellent variety. It flowers very late, and so escapes late frosts. Long bunches of bright shining red berries are formed, the individual berries being very large and uniform in size. When gathered it has a very fine appearance and commands the top price in the market.

Price **8d.** each; **7/-** per doz. Extra strong **1/-** each; **10/-** per doz.

Collection of Roses

COLLECTION "D"

Consisting of Twenty-four Dwarf Roses, specially selected to succeed in any position where Roses will grow, we can recommend all the varieties; they will give pleasure in any garden.

The Collection of Twenty-four Dwarf Roses, *Carriage* and *Packing Free* for the sum of **32/6** The Varieties are:—

Seedsman and Florists to H.M. The King,
EDINBURGH.

BEAUTIFUL VELVETY LAWNS

That is how they are often described in novels, but how seldom do they come up to the ideal? Instead of being "velvety" they are often brown or patchy and full of weeds. What is the remedy for poor lawns? Many things contribute, such as mowing, rolling and weeding, but the most important point is to **regularly manure your lawn** with a suitable Grass Manure, and the very best preparation for the purpose is

PEARSON'S

ANTI-CLOVER MANURE

which will discourage the growth of clover and weeds and will encourage the finer grasses.

Southwark St.
LONDON. S.E.1.

"Look at his garden!"

Yes, look at it. Did you ever see a finer show for this time of the year? How is it he gets a profusion of early blooms weeks before anybody else? Why is it that his vegetables and fruit-trees never fail? He looks after the soil—strengthens it with ECLIPSE Fish Manure. Plants want nourishment—food as well as water—and few soils contain all the nourishment required. ECLIPSE Fish Manure enriches the soil—gives you hardy plants, deep-coloured blooms, and a garden flowering continuously nearly all the year round.

ECLIPSE Fish Manure contains Phosphates, Nitrogen and Potash in their proper proportions. Being largely organic, it supplies humus to the soil.

garden I'd like"**

"Strong hardy plants, flowering nearly all the year round, as fine a bed of vegetables as you'll find within a few miles, and fruit trees that never fail. I can't get anything like the same results in my garden."

But you can. Use **ECLIPSE** Fish Manure and you will.

Think a minute. Realise that you're starving your plants and trees. The soil is poor. It gives insufficient nourishment. It lacks certain essential properties without which plants cannot thrive. Enrich the soil with **ECLIPSE** Fish Manure—and you'll get bolder plants, a profusion of deep-rich-coloured blooms and a good crop of fruit and vegetables, year after year.

ECLIPSE Fish Manure contains Phosphates, Nitrogen and Potash, in their proper proportions. Being largely organic, it supplies humus to the soil.

CORRY & CO., Ltd., Shad Thames, LONDON, S.E.1**BEAUTIFUL VELVETY LAWNS**

That is how they are often described in novels, but how seldom do they come up to the ideal? Instead of being "velvety" they are often brown or patchy and full of weeds. What is the remedy for poor lawns? Many things contribute, such as mowing, rolling and weeding, but the most important point is to regularly manure your lawn with a suitable Grass Manure, and the very best preparation for the purpose is

PEARSON'S**ANTI-CLOVER MANURE**

which will discourage the growth of clover and weeds and will encourage the finer grasses.

BLACKMORE & LANGDON, Bath.

BATH'S Border Carnations, Etc.

FOR PRESENT PLANTING.

We make a great speciality of Carnations, and our stock is
unequalled. The plants are very strong, perfectly hardy,
and will satisfy the most fastidious buyer. The following
sets are selected from our unsurpassed collection of 250 varieties
and contain the cream of the new and older sorts.

SET No. 6.

Twelve extra fine varieties for 14/-, carriage paid.

Celestial—brilliant yellow self.
Delight—bright pink; grand form.
Elaine—a grand white; perfect form.
Gordon Douglas—glowing crimson.
Salmon Clove—rich salmon-pink; fragrant.
Rosa Bonheur—yellow, suffused crimson.
Caprice—pink, mottled red.
Centurion—yellow, splashed scarlet.
Ariadne—bright heliotrope; extra.
My Clove—apple-blossom, shaded helio.
Isolde—raspberry-red; extra.
Glow-worm—brilliant scarlet; dwarf grower.

SET No. 7.

One dozen choice varieties for 10/6, carriage paid.

Beau Nash—charming shade of rose.
Glamour—large yellow self.
Innocence—a lovely blush-pink.
Bookham Clove—bright crimson; fragrant.
Climax—buff, suffused old rose.
Trojan—glistening pure white.
Dignity—a lovely deep shrimp-pink.
Lord Tennyson—yellow, edged rose.
Duchess of Wellington—deep lavender.
Queen Alexandra—buff-yellow; very free.
Red Knight—bright salmon-scarlet.
Santa Claus—yellow, edged purple.

BATH'S POPULAR SET

of 12 fine named varieties of Carnations and Picotees.
Price 8/6, carriage paid.

The three above Collections complete for 31/-, carriage paid

BATH'S Gold Medal PÆONIES

Pæonies are the most gorgeous of all garden flowers. They
are exceedingly hardy, and when once established require less
attention than almost any other plant. Many of the blooms
of the following varieties attain a diameter of 10ins. and nearly
all are beautifully rose-scented.

Twelve glorious richly fragrant varieties for 22/6, carriage
paid.

SET No. 3.

Albert Crousse—pinkish-blush; enormous flowers.
Golden Harvest—blush, white centre, tipped red.
Duchess de Nemours—snow-white; free.
Festiva Maxima—pure white, tipped purple.
Marie Lemoine—pure white; late.
Mme. Calot—white, tipped rose; extra.
Mons. C. Leveque—a lovely silvery-blush.
Dainty—rosy-blush, showing golden anthers.
Solfaterre—beautiful primrose-yellow.
Mme. Ducet—soft salmon, with silvery shading.
Victor Hugo—brilliant amaranth; delightful colour.
Reine des Francaise—outer petals rose, white centre.

SET No. 4.

Our selection of 12 very fine named varieties, mostly
fragrant, for 15/-, carriage paid.

BATH'S GOLD MEDAL DELPHINIUMS

These plants are remarkably handsome in the border, and
during the early summer and autumn the bold and stately
masses of brilliant blue and purple produce a striking effect
unequalled by any other flower.

SET No. 2.

One doz. extra fine varieties for 21/-, any 6 for 11/-,
carriage paid.

Arnold Bocklin—brilliant gentian-blue.
C. W. Matthes—rich pure blue; light and dark stamens.
La Tendresse—light blue and mauve.
Willy O'Brien—pure corollower-blue, mauve centre.
Turquoise—pure Cambridge-blue, dark eye.
Rozenlust—light mauve, edged Cambridge-blue.
King of Delphiniums—gentian-blue and plum, white eye.
The Alake—intense dark blue, violet centre.
Zuster Lugten—pure Cambridge blue, silvery shade.
Roselare—corollower-blue, tinted aëratum-blue.
K. T. Caron—gentian-blue, suffused mauve.
Ida R. Elliott—dark cobalt-blue, amethyst centre.

BATH'S POPULAR SET

of 12 fine named varieties Delphiniums for 10/6, carriage
paid.

Complete Illustrated Catalogues post free on application.

[MARCH 10, 1923.]

GRACE IN THE SHRUBBERY

THE most useful of all families of shrubs is that of the Rhododendron, but alas! they are very stolid, so for that matter are most of the so-called American plants. The garden forms of the Common Lilac are not specially graceful, nor are Staphylea, Osmanthus and a host more.

It will be appreciated, then, that shrubs of lighter, less solid outline are important if only for the sake of variety; and from another point of view, shrubs which display their blossoms in graceful sprays have a claim upon our attention. One of the most solid and stolid-looking of flowering shrubs is *Spiræa Bumalda*, yet the shrubby *Spiræas* as a family are not wanting in grace—even in lightness. One of the most graceful shrubs we have when in blossom is *S. prunifolia* fl. pl., and *S. arguta* lags little behind. The grace of *SS. Lindleyana* and *ariaefolia* is undeniable, yet both are eclipsed by the lovely Pearl Bush, *Exochorda grandiflora*, and the somewhat similar *E. Alberti macrantha*.

Common Lilac was mentioned as an example of a heavy-growing shrub, yet some species of *Syringa* are as light and airy in growth as one could wish. Such are, for example, *SS. persica*, *sibirica* and *Wilsoni*. The same contrast is observable in the genus *Escallonia*. *EE. macrantha*, *rubra*, etc., are heavy shrubs very suitable for solid planting, but the deciduous *E. Philippiana* and all its derivatives—*EE. langleyensis*, *Edinensis*, *Donard Seedling*, etc.—are as light and graceful as can be.

All the Mock Oranges are graceful, but the single forms surpass the double ones in this respect, and those with the flowers spaced a little apart are incomparably more gracious than those

of which the blossoms are bunched together. *Coupe d'Argent*, illustrated on the next page, is particularly graceful among the smaller-growing varieties, while *Virginal* is noteworthy among the bigger growers.

The grace of *Berberis stenophylla* needs no emphasising. It is, indeed, its gracefully arching shoots which ensure its popularity, for in colouring it cannot compare with the glorious orange of *Darwinii*. This is the only really graceful Evergreen Barberry, although the pleasing spacing of the "lanterns" on *B. buxifolia* makes it gracious when in blossom.

The arching canes, if such we may call them, of *Prunus triloba* are very graceful, yet they seem stiff alongside any of the hardy Fuchsias of the *myrtifolia* clan. *Fuchsia Riccartoni* is much less graceful.

Gracefulness is not necessarily associated with an arching or weeping habit of growth. Some

of the flowering Cherries prove the contrary, but shrubs or trees which naturally form round, close beads—the Mop-headed *Acacia*, *Robinia Pseudacacia inermis*, or the whole Thorn family, for example—may glow with the most brilliant colouring of flower or foliage, but they will not attract like the forms of *Wistaria multijuga* or the better forms of *Golden Chain*, *Laburnum Parksii*, for instance.

Some plants are graceful or not according as they grow well or ill. The illustration on this page shews *Viburnum tomentosum plicatum* in such form that everyone must admire it, but it does not always grow so. To get the long arching shoots seen in the picture, the shrub must make vigorous, arching canes each season. The *Viburnum* family varies considerably as regards grace. None of the evergreen species is slender or graceful—perhaps *V. rhytidophyllum* is the stolidest and ugliest of all—yet the single Guelder

Rose, *Viburnum Opulus*, is gracious, and even the double Snowball tree has an elegance of its own. Most gardeners now consider *Viburnum tomentosum Mariesii* better than the sterile *plicatum* form we illustrate, but much depends upon soil and situation.

The arching growths of *Hydrangea paniculata* do not suffice to give it a lightening influence when in flower. The heavy panicles in a rather heavy tone of greenish white prove just as "lumpy" as those of the *Hortensias*. Another shrub which is improved by cutting back each year, *Buddleia variabilis*, is, however, graceful enough, and it draws added grace in the sunlight by attracting a multitude of coloured butterflies. There are many forms of the plant in

THE JAPANESE "SNOWBALL TREE," *VIBURNUM TOMENTOSUM PLICATUM*.

ONE OF THE BEST SMALL MOCK ORANGES, PHILADELPHUS COUPE D'ARGENT.

THE BEAUTIFUL AND GRACEFUL CYTISUS PRÆCOX.

A FINE FORM OF BUDDLEIA VARIABILIS.

cultivation, and some are much more worthy than others. The two best, so far as our experience goes, are called *magnifica* and *superba*. Though rather different in appearance, *magnifica* is a shade deeper in colour and longer and narrower in the panicle, both are equally valuable, but *superba* is perhaps a fortnight later to flower. The form *Veitchiana* introduced by Wilson is hardly so fine as either, but it flowers a little earlier than *magnifica*. If a group of the different varieties of this species is planted, the seedlings will vary greatly in colour, season and form of the panicle. *Buddleia variabilis* comes freely from self-sown seeds, and the seedlings are usually quite worthy as far as size of truss and habit of growth goes. Perhaps this peculiarity accounts for the undoubted confusion which exists in nurseries as to the different varieties. The fine form illustrated on this page is called *ampleformis*.

Some Rose species are exceedingly graceful, not only when in flower, but at all seasons. The Dog Rose has, we all know, a graceful habit of growth, so has the white-flowered "Blue-briar," *Rosa arvensis*, but neither is suitable for the shrubbery. The Sweet Briar (*R. rubiginosa*) is more amenable to cultivation and almost equally graceful in habit of growth. Most of the Penzance Hybrid Briars take after it in this respect, but the branches are heavily armed, and if they are used they should form a group of themselves apart from other shrubs, otherwise they render weeding, pruning and other routine work difficult.

Of quite a different and more slender habit of growth are the Roses of the *macrophylla* section—*R. macrophylla*, *Fargesii* and *Moyesii*. All these are handsome both in flower and fruit. The hips, indeed, are the most distinct in the family, for the persistent calyx swells out beyond a narrow neck, giving the fruits a bottle-like appearance. The bright yellow *Rosa Hugonis* is another graceful species. The same may be said of the various forms of the Musk Rose, *R. moschata*, though some support should be afforded these, as they love to clamber and will, indeed, climb a far-sized tree. The hardiest form of this Rose is usually listed as *R. Brunoni*, but the double hybrid called *The Garland* seems perfectly hardy and has most of the characteristics of the parent.

Rosa multiflora is a species which loves to have its roots in shade. It is therefore much at home in shrubberies. The species is white flowered, but the *multiflora* Ramblers, which before the advent of the *Wichuraiana* hybrids were so popular in gardens, all share its love of the shrubbery. The beautiful *Blush Rambler* comes to mind as one of the best and most graceful, but, at the season when it flowers, *Crimson Rambler* can usually have the shrubbery to itself as far as blossom goes, and is then most effective.

Many of the Brooms, particularly those belonging to the genus *Cytisus*, are as light and graceful as shrubs well can be. The Common Broom, *C. scoparius*, is graceful when young, but becomes solid and stodgy with age. The same may be said of its varieties, such as the gold and white *Andreas* and the sulphur-coloured *Moonlight Broom*, *C. scoparius sulphureus*. The White Broom, however, *Cytisus albus*, retains its grace throughout life. It is, besides, a much longer-lived plant than our English Broom. Almost as graceful and even more pleasing in colour is *Cytisus præcox* with sulphur yellow blossoms. Equally graceful in quite a different way is *C. lewisii*, which might be described as a prostrate *C. præcox*. For cascading over ledges or rock or adorning a bank this is an ideal plant. Even for the margin of the level shrubbery it is a fine thing.

WATER AND BOG GARDENING

III.—Plants that Grow in the Water

BYOND all question Water Lilies should occupy by far the largest space of the available water surface; but, good as they are, I would enter a strong plea for reasonable representation of the various other beautiful flowering and foliage plants that do so much to complete the perfect picture. Selection of varieties is very difficult where so much is desirable, but we must excise and narrow down until we have brought the proposals into line with the capacity of our garden. Happily, we are helped somewhat in this direction by the size of our pond and the depth of the water, for we must adapt our plants to these conditions and so—unless the area is very large indeed—certain things rule themselves out as too vigorous

L. liliacea, a large and sweetly perfumed form, a lovely rosy lilac with orange stamens, notable for the length of its flowering—June to November. *L. purpurata*, very fine indeed, a lovely purple that fades into crimson towards the centre. *L. rosea*, perhaps the most attractive of all, for, in addition to the bright carmine rose flowers with orange stamens, there is the beautiful coppery red foliage. Extremely free, very long flowering and prominent for its fragrance. One of the *Marliacea* hybrids is especially useful for shallow water—*M. ignea*. This is the opposite of the *Laydekeri* varieties in that the blooms open their deepest colour and gradually pale from day to day until they fade. Its colour is a deep red with fiery red stamens and, although it grows

in praise of *sanguinea*, a free and continuous bloomer of moderate growth with bright crimson flowers that later become deep blood red with light orange centre. Attractive in both flower and foliage is *Seignoureti*, a fine orange red variety with golden centre, the flowers of which are splendidly erect. The leaves are large, bright green and maculated all over the surface with purple brown. Additions are constantly being made to these delightful plants in the form of new hybrids, and with such a wealth of splendid varieties one wonders sometimes where it will end or if, indeed, there is any finality.

The beautiful *Nymphæa stellata* and the equally lovely *zanzibarensis* forms are readily grown outdoors in summer if some method is adopted of heating the water of the pond. This is often feasible on a house terrace.

Leaving the Water Lilies, we come to the "others," a very varied race indeed. *Alisma natans* is the floating Water Plantain, a rare native plant that is, however, readily obtainable through the usual trade channels. It is of very neat habit of growth, with oval leaves and showy three-petalled white flowers on leafy stems. *Azolla caroliniana* is of microscopic proportions and loves a stagnant place well to the side of the pond, for, when all is said and done, it is little more than a wee moss floating on the surface. During the earlier periods of its growth it is bright pale green, but becomes purple with age. The Water Violet, *Hottonia palustris*, well substantiates its claim to being one of the most beautiful of our native aquatic. The growth is in the form of a submerged fern-like foliage dark bright green in colour, with flower-scapes rising upwards to a height of 1ft. and bearing whorls of pale mauve flowers. The Frog-bit, *Hydrocharis morsus-ranae*, is another small floating plant suited to even the smallest rock pool, with elegant little kidney-shaped brown leaves. It can be relied upon to spread quickly over the surface of the water.

The Water Poppy, *Limnorchis Humboldtii*, makes a most attractive plant of very neat growth, with broad oval leaves resting upon the surface of the water, and flowers, on long stalks shaped like the Poppy and pale sulphur yellow in colour. This is only hardy in favoured places, and a note should be made to take it up in autumn, and winter it in the greenhouse. One of the *Nuphars*, *N. luteum* var. *minor*, is a useful little plant for the small pond, where it soon forms a good patch of its small surface-floating green leaves and a profusion of deep yellow flowers. *Ranunculus circinatus*, the Water Crowfoot, is a small enough grower for the tiny pond and especially useful, as it flowers in spring with a profusion of small white blossoms. *Typha minima* is a miniature in every way of the Lesser Reed Mace, of erect, sturdy habit and splendid for the small pond, where it rises to a height of 1ft. to 18ins. above the water. The common Bladderwort, *Utricularia vulgaris*, an interesting little native plant which should not be overlooked, for its finely divided submerged flowers, furnished with minute air bladders, are most interesting, to say nothing of the pretty scapes of yellow flowers that rise about 6ins. above the water. *Vallisneria spiralis* bears small floating leaves similar to those of the Water Lilies and myriads of yellow flowers like the *Ranunculus*. H. W. C.-W.

(To be continued.)

NYMPHÆA STELLATA IN AN OUTDOOR HEATED TANK.

and spreading. I propose, therefore, to deal with our plants under two headings.

The first of these to consist of plants that are suitable for ponds where from 6ins. to 2ft. of water is available, and the second where there is from 1ft. to 3½ft. *Nymphæas*, of course, come first in both cases, and of those that are suitable for the small pond, tank garden or tub culture the following are all good: *N. Ellisiana*, large-flowering and sweetly scented, producing very freely its brilliant carmine purple blooms; *fulva*, orange tinted with golden yellow, the petals claw-like and—again—very fragrant; *Graziella*, very distinct and free, with medium-sized flowers, orange red in colour with crimson stamens. The *Laydekeri* group are *pygmæa* hybrids, characterised by small foliage and medium-sized flowers, every one invaluable for tub, shallow pool or tank culture. An interesting feature of these is the change that takes place in the colour as the days pass, for when in their youth the colour is always pale, deepening with each day that passes. *Laydekeri fulgens* is distinct and very beautiful, rich amaranth red with orange centre.

well in shallow water, it must have sufficient space, for it spreads widely; while, too, the natural habit is to throw the central leaves above the water.

All the *odorata* varieties are valuable, but must have sunny and sheltered spots to do well. The flowers are extremely shapely, with incurving petals, though it must be confessed that it is a pity that they close so early in the afternoon. Varieties are quite numerous, and among these a note should be made of *o. exquisita*, bright rose with yellow stamens, of moderate growth; *o. luciana*, medium sized, carmine rose; *o. maxima*, large white, tinged with flesh pink; *o. sulphurea*, sulphur yellow, powerfully fragrant, with wonderfully marbled leaves. *Pygmæa* is the smallest of the family, with leaves that do not exceed 2ins. or 3ins. in width and pure white flowers very freely produced. *P. helvola* is a form of this, with very fragrant pale primrose flowers and dark green leaves that are prettily spotted with reddish brown. Both of these are superb for growing in the basins of fountains, and in this connexion, too, a word must be said

LILIES OF A DECADE: 1912-1922

IN 1912 *Lilium regale* received the award of merit. I remember thinking at that time that it was one of those flowers that look too delicate for the garden out of doors. To-day it has become well known for its hardy constitution and the freedom with which it flowers and seeds. Moreover, it has revealed

horizontally or slightly drooping. The stems are about 1½ ft. to 4 ft. high, and are densely covered with long, narrow leaves. From year to year it is becoming better known and more common, and there is little doubt that it will ultimately vie with the older *Madonna Lily* for first place in the garden. In America it is grown largely

feet to 7 ft. high stems, bearing from six to fifteen flowers that appear to be something between *sulphureum* and *Brownii*, but with the length of the tube in one, blended with the breadth of the other, and perhaps larger than either. It is white, flushed internally with yellow in the narrow end of the trumpet, and externally each petal is shaded

CHARMING AND EASY—*LILIIUM PHILIPPINENSE FORMOSANUM*, PRICE'S VARIETY.

THE SPLENDID MANY-BLOSSOMED *LILIIUM CENTIFOLIUM*, MAINLY WHITE IN COLOURING.

to many people who would never have thought of sowing seeds how easily it and other members of its large family can be raised from seed. It has been so often described since those days that detailed analysis of its charms is no longer necessary. It is one of those lilies that are generally described as funnel shaped, but at certain angles appears to go some way towards the trumpet shape. The ground colour is white, but it does not give an impression of pure white. This is due to the fact that the interior is faintly tinted in a varying degree with very pale yellow, and the exterior is shaded with a brownish red tint that extends throughout the length of the petals, but gradually pales to pink near the lower portion. The petals being translucent, this colour shows through them and gives the portion of the interior that is not yellow a faint pink tint. The texture of the flower is silky, and the result is that the interior suggests pearls that are faintly flushed with pink. It rarely produces more than four flowers on each stem, and these are borne almost

for florists' work, and in this country it is not unknown to the best florists, but the supply is not sufficiently plentiful to make it popular. Out of doors or as a pot plant it is equally successful. Its flowering period, July, can be anticipated by several months by gentle forcing, and if there were enough of it there should be no difficulty in retarding it for winter use. It was collected by Wilson in China, and the award of merit was subsequently raised to a first-class certificate in 1915.

Another Lily that came into the public eye in the same year was *warleyense*, which was also given a first-class certificate, but its name has since been determined as *Willmottii*. Though it may never be as plentiful as *regale*, it has a really good constitution, and won its way to the hearts of all garden lovers by its light, slender habit and the graceful carriage of its brilliant orange red flowers, which is enhanced by the slenderness of its foliage.

Perhaps the most startling introduction of the last ten years is the wonderful *centifolium*. Six

deep crimson brown down the length of its centre, which shades quickly away towards the edges to a pale brownish red mingled with white. Lilies as a genus have no particular love for chalky soils, but this has been known to do well in such conditions and grow 6 ft. high, bearing as many as fifteen flowers. It received a first-class certificate under the description Farrer's No. 316. It was found by the late Mr. Reginald Farrer in a cottage garden in China during his first expedition. It is still scarce in commerce, although there are a few private gardens with quite a nice little colony of it.

Of quite different characteristics is the much smaller-habited *L. philippinense formosanum*, Price's variety. Found at an altitude of some 8,000 ft. in Formosa, the authorities have expressed certain doubts as to its correct name, and the result is that it has to be labelled with a cognomen that contains many more letters than the plant has inches in stature. In some respects it is, unlike any other Lily. None has the great length

of tube in proportion to the size of flower. No other has the dainty grassy foliage of a brilliant luscious green. None flowers quite so quickly from seed, not even regale. The length of the tube of its trumpet-shaped flower is very remarkable, and the purity of the white internally is beautifully contrasted to the deep ruddy brown that marks the central midrib on each petal externally. It received the award of merit in 1921, although it had been known in gardens for some time previously.

Two new Lilies that were shewn for the first time in 1921 that have some points of resemblance, although they are in many ways distinct, are hybrids obtained by crossing Martagon and Hansoni, the latter being, of course, a "Martagon" in type itself. Only two have so far been exhibited, although there is a wonderful variety in the remainder. Both are giants, 5ft. to 6ft. high, and bearing anything up to about thirty flowers on a stem. Mrs. R. O. Backhouse is orange yellow with pronounced purple spots, and its companion, Sutton Court, has the same yellow groundwork, which it, of course, gets from Hansoni, but in this case the yellow is flushed with pink, and the spots almost amount to blotches of deep purple brown. The constitution appears to be as good as that of either of the parents, which is saying a great deal, as the Martagon (the Turk s-cap Lily of the old English garden) is perhaps the most persistent of the genus in the garden of to-day.

Another hybrid, or almost a race of hybrids, seeing how variable it appears to be, is sulphureum, obtained by crossing the July-flowering short-flowered regale with the late September-flowering sulphureum, a very long trumpet-shaped flower. This was an ideal cross, and had the results been more carefully preserved its popularity would not have been so tardy. But it is unfortunately the case that most of the bulbs in commerce are seedlings from the original hybrids, and there has been a certain amount of reversion to type among them. Some are little removed from regale, but where the selection has been careful and the truly intermediate type is obtained, it is indeed a wonderful plant. Both parents having yellow in the interior, this, of course, remains in the children, but the most noticeable effect has been to lengthen the flower-bud until it approaches that of sulphureum. Stature has been added to regale, the flowering period of regale has been retarded for several weeks, the size of the flower increased, and the colouring is so exactly balanced between the two that one hardly knows whether to call it a late regale or an early sulphureum. On the whole, however, the balance is in favour of calling it a later, much improved and larger regale.

The first of the last two that I shall notice among Lilies of ten years is Farreri, which Mr. Farrer himself called the "Marble Martagon." It is a slender-stemmed Martagon about 3½ ft. high with several white flowers that are internally spotted with purple. Perhaps it is rather for the specialist than the ordinary gardener, although its constitution is quite good. It, however, lacks that highly decorative quality that goes to make flowers popular except with the understanding few.

Lilium pseudo-tigrinum is a garden Lily of the first order. Its tall, slender stems, with numerous orange reflexed flowers (5ft. high and carrying twenty flowers is a common experience) is altogether the finest thing in its class of recent introduction. Found by Mr. Forrest during one of his earlier expeditions, it has become a well known garden plant, and is likely to become more popular still. Its wonderful orange red flowers, an orange that deepens to crimson in well defined points over a

portion of the interior of the flower, are quite sufficient in themselves to attract attention to its merits, but its exceeding grace of carriage and dainty narrow foliage ensure for it a place in the hearts and gardens of all flower-lovers.

Other Lilies there have been during the last ten years, but not many of them are for the average gardener. Beautiful they are or were, for Lilies come and Lilies go, but not all go on for ever. There was that wonderful cross between auratum

and speciosum made by Mr. Hayward. In itself it was a glorious plant, but it has apparently disappeared from mortal ken. For years certain species cease to be obtainable, and then some fortunate circumstance brings them back to the knowledge of mankind. Many beautiful hybrids have seen the light of publicity for a short year or two and then gone to a bourne from which they never return, leaving nothing but the fragrance of a memory. These were not for the great world of garden-lovers but for the select few. G. D.

THE BORDER CARNATION

THOSE who have not procured and put out plants of any new varieties of Border Carnations they may want for the border should do so without delay. Ground in thoroughly good heart should be reserved for these plants in an open, sunny position. That it should be free from wireworms and other insect pests goes without saying. The Carnation abhors hollow ground, so that planting should be done when the ground is in nice planting condition and be made firm around the plants. As a rule, soil which really suits Roses and Strawberries will suit Carnations also. Fresh manure should never be applied to the Carnation-bed, for the Carnation is anything but a gross feeder, but the addition of some old mortar-rubble is advisable. Attention has lately (and very wisely) been focussed upon the new race of hardy clove-scented Carnations, or, as they are more familiarly called, "Border Cloves." This appreciation of the Clove must not, however, cause us to overlook the very real advance that has been made of late years with the ordinary Border Carnation. That this advance is not appreciated by everyone is obvious when one sees the numbers of gardens in which the Border Carnation finds no place. Were the absolute hardness, floriferousness and dwarf habit of the newer varieties thoroughly understood, the popularity of the flower would increase by leaps and bounds.

Lists of standard varieties have often appeared in THE GARDEN. We will on this occasion content ourselves with mentioning a few of the best novelties. King of Cloves is probably the best Clove-scented Carnation so far produced. It is a deep glowing ruby crimson shade of fine shape and good size. The plant is an exceptionally strong grower, the stems are as stiff as could be wished, and the calyx does not split. Scarlet Clove is a fine flower, a good grower, and has also a perfect calyx, but its colour

is hardly scarlet except, perhaps, as it opens. The expanded flowers are coral red. This is a good and showy variety. Other noteworthy novelties (not Cloves) include Kelso, a wonderful fancy variety, the colour being reddish apricot striped with greyish purple; Viceroy, a splendid flower, has deep carmine-crimson streaks and edges on a rich yellow ground; Maréchal Niel is a huge and handsome soft yellow self; Lomond Hills, primrose yellow edged and marked greyish heliotrope—a fine border plant and unique in colour. The above are a selection of Mr. Douglas' novelties. Messrs. Lowe and Gibson are sending out Jessie Murray, which is milk white flecked

BORDER CARNATION VICEROY, CARMINE AND YELLOW.

with lavender and fragrant. This rather reminds one of the new and happily named Perpetual variety Chintz. Jessie Murray is free to flower and of excellent habit.

SPRING FLOWERS AT VINCENT SQUARE

ON each succeeding occasion the Royal Horticultural Society's meetings become more spring-like in character, and this, with the bleak weather of February 27 last, was very grateful. Messrs. Carter and Co. had a very artistic display of spring bulbs, and their many Tulips made a splendid show. The shallow basket of Tulip Prince of Austria was especially striking.

Messrs. R. H. Bath, Limited, had a rare lot of bulbs in fibre, including excellent Hyacinths, Tulips, Daffodils and Snakesheads.

From the true Daffodil-lover the superb collection of Messrs. Barr and Sons demanded most attention. It is safe to say that never before have so many excellent seedlings been on view. Their seedling Trumpet varieties were superb in the quality of the floral segments and the richness of their colours. Besides these there were two blooms of Incomparabilis seedlings of great size and possessing large coronas of intense fiery orange colours. Of their named Trumpet varieties the very best were Anyata, Alicia and Yorick. Adjoining the Narcissi were branches of Cydonia

cardinals and C. Simonii, bearing crimson flowers, and the blush pink Aurora. A splendid collection of pot Hyacinths was set up by Messrs. R. and G. Cuthbert. The King of the Blues were very fine, as also were the spikes of the paler blue Enchantress, Jacques and King of the Reds.

Rhododendrons were very effective, even though most of the trusses came from Cornwall. Messrs. R. Gill and Son had many trusses of the vivid crimson Cornubia, with the blush Florence Gill and the white bell-shaped argenteum. In a collection of mixed flowers and plants Mr. G. Reuthe had Rhododendron arboreum seedlings and a good pale pink named R. prævernum.

Saxifrages were plentifully shewn by the exhibitors of alpine, and among these it was those with pink flowers that attracted most admiration. Saxifraga Irvingii in the collection of Messrs. Bunyard and Co. was larger, though paler in colour than usual. Deep pink colour was present in the flowers of S. Wetterhorn, shewn by Messrs. Maxwell and Beale, and also in S. oppositifolia splendens, in the collection of Messrs. R. Tucker and Sons; while Mr. W. Wells, jun., shewed the variety Latina, which bears plenty of flowers of pleasing rosy mauve colour. Rich colour was also present on the bracts of S. Grisebachii Wisley variety, which was shewn in quantity by Mr. Clarence Elliott. Goodly batches of S. Elizabethæ and S. apiculata in the same exhibit were masses of soft yellow colour.

Hepaticas, which are much rarer in gardens than a quarter of a century and more ago, were to be seen in several collections of hardy flowers, and Mr. F. G. Wood also had desirable clumps of the old-fashioned double mauve Primrose. He also shewed little bushes of Daphne Mezereum with stems circled with flowers. At one end of his exhibit Mr. Wood had a few of his exceedingly useful optical squares by which right angles may easily be set out when laying out fresh features in the garden.

Polyanthuses of great merit were staged by Mr. G. W. Miller, and the Chalk Hill Nursery Company, Reading, had several pans of Primrose True Blue, of uncommon sky blue colouring, and they also had pans of Cyclamen Coum rubrum of rich deep colour. Deep blue colour was seen in the flowers of Pulmonaria azurea in the little spring garden of Messrs. J. Cheal and Sons.

A large number of gently forced bushes of the fragrant Viburnum Carlesii, together with Osmanthus Delavayi, Pyrus floribunda and various Brooms were well shewn by Messrs. Wallace and Co., and the Azaleas of Messrs. L. R. Russell, Limited, were very effective. At one corner they had a small pot plant of Orange Otaheite unusually well flowered.

A large collection of splendid Cinerarias was set up by Messrs. Sutton and Sons with all their usual taste and skill. The large stands of pink shades were very effective, and the Forget-me-not Blue variety was most appropriately named. Rich glowing colour was provided by the velvety blooms of Superb Scarlet and the graceful stellata varieties were also well represented.

The first Roses of the season were shewn by Mr. Ulisha Hicks, and among them was a vase of Gruss an Aachen, a sweetly fragrant Rose somewhat reminiscent of Gloire de Dijon, but quite distinct in foliage. Carnations, as ever, were largely shewn.

Mr. R. A. Malby had a very specially fine collection of photographs of flowering shrubs, and also beautiful coloured transparencies of many different plants and of garden scenes. The transparency of the glowing Rhododendron Ne Plus Ultra exhibited at the previous meeting

SUTTON'S CINERARIA FORGET-ME-NOT BLUE.

HUGE PALE BLUSH BLOSSOMS OF RHODODENDRON CILIICALYX.

attracted much attention. One could fancy one was looking at the flower itself. The whole exhibit was almost as interesting as the collection

Narcissus Golden Herald.—The award was primarily in recognition of its merits as a garden Daffodil, but it should also prove to be a large trumpet variety eminently suitable for market purposes. It is much earlier than King Alfred, to which it bears a little resemblance. It is of rich yellow colour, of large size and substantial texture. Award of merit to Messrs. Barr and Sons.

Rhododendron cili calyx.—This tender species is closely allied to *R. formosum* and *R. Veitchianum* and, like them, is pleasantly though not so strongly fragrant. It was introduced from China in 1900, and differs from the above named chiefly in having a more robust habit, larger flowers and hairs on the calyx. The trusses of white flowers, which have lemon-yellow throats, are very beautiful. Award of merit to the Curator, Royal Botanic Gardens, Oxford.

Rhododendron strigil-losum.—In brief this might be termed a narrow-leaved deep crimson *Rhododendron arboreum*, and it appears to be as hardy as that well known species, but, like it, is liable to injury from severe frosts. The variety is quite distinct in its densely hairy stems and the golden brown tomentum along the undersides of the mid-rib of the leaves. Award of merit to Lady Aberconway.

Saxifraga R. V. Prichard.—At a first glance this would seem to be a less milky white than *S. Burseriana*, but it differs in having a green base to the petals and a small crimson band around the filaments, giving the appearance of a crimson eye. This struck us as scarcely worthy of award. Award of merit to Mr. M. Prichard.

Cymbidium Alexanderi Rosalind.—This is a chaste and beautiful Orchid. The venation of the waxy sepals is lightly flushed with rosy purple and there is a slight sheen of similar flushing on the young flowers. The lip is stained with rosy carmine. First-class certificate to Sir George Holford.

Cymbidium Auriga.—This also is an uncommonly beautiful variety. The general colour is a glowing golden buff, occasionally very lightly flushed with rosy purple. The lip is narrowly margined with white, and next comes a narrow line of stippled rose pink. First-class certificate to Messrs. A. and J. McBean.

Cypripedium Senator.—This is an immense Lady's Slipper Orchid which may be termed a much glorified *Cypripedium insigne*. The large white standard has a distinct pale green base and has prominent chocolate spotting. It is a green-leaved variety. Award of merit to Messrs. Flory and Black.

Odontioda Coligne Rosmary.—A magnificent spike of well formed flowers of gorgeous deep

crimson colour, paler at the edges. There is a golden crest and the segments are lightly blotched with white. Award of merit to Mr. J. J. Bolton.

Odontioda Rufus Wickham Beauty.—A short, erect spike of three large blooms of cloudy, deep crimson colouring which pales considerably towards the margins of the flowers, becoming an apple-blossom pink. Award of merit to Mr. J. W. Bird.

"QUEENS' GARDENS"

THE "old" annexe at Olympia is again given up to gardens designed by Royalty for the Ideal Home Exhibition. The construction of these gardens has been carried out by English nurserymen. Princess Mary Viscountess Lascelles has chosen an undulating woodland scene, and rockwork has been introduced (Sussex sandstone). To complete the picture a rock pool has been added, together with a powerful waterfall of the usual "exhibition" type, which, again as usual, destroys the repose and proportioning of the garden. Messrs. Pulham and Son are responsible for this.

A more restful spring garden, to the design of Her Majesty Queen Alexandra, has been constructed by Messrs. James Carter and Co. Here are to be found drifts of yellow and white Daffodils and a rock pool with a gentle waterfall. The weather-worn rock with Ferns growing by helps to make a pleasing picture. Other flowers in this spring garden are Tulips, Polyanthus in various colours, Snowdrops, a drift of *Erica carnea* and *Prunus triloba*. The whole is backed with conifers, while Bamboos are also in evidence.

A blue garden is apparently favoured by H.R.H. Princess Alice. This takes the form of a raised formal garden with a sunken circular fountain, and has been carried out by Messrs. R. Neal and Sons. The flowers employed are blue Cinerarias and blue Hyacinths—not an ideal combination for this climate!

A Spanish fountain garden of Moorish design is the choice of H.M. the Queen of Spain. The garden is, naturally, exotic in appearance, and the mollis Azaleas are somewhat startling in colour, ranging as they do from pale yellow to salmon. However, the garden in a congenial environment would no doubt be very beautiful. It is paved with red tiles, and is entered by a fine Italian wrought-iron gate supported by quite inadequate piers. Mr. G. G. Whitelegg, who has carried out the construction, is fortunate enough to have in his possession two very fine old stone seats, and these he has admirably placed just inside the garden. This garden is surrounded by a rough white Moorish wall. A garden house, also in roughcast, with wooden beams across the top terminates this quaint garden. Apart from this garden Mr. Whitelegg has made a small rock garden, which is skillfully planted with such plants as Saxifrages, including *S. Elizabethæ*, *Iris bucharica* and *I. orchoides*. Dwarf conifers have also been introduced. Constructed of Yorkshire stone this garden is attracting much attention. It should make special appeal to those whose gardens are somewhat limited in area.

Messrs. W. H. Gaze and Son have made for H.M. the Queen of the Belgians a formal garden surrounded by a Yew hedge. A long, narrow sunken pool runs down the centre of the garden, and is edged with *Iris tingitana* and white Arums (*Richardia*) are employed in the water. A fine old stone seat is at one end of the garden. An Italian wrought-iron gate at the side gives entrance to this garden, which is very restful and pleasing.

Further particulars of the gardening side of the Ideal Home Exhibition will appear in our next issue

LIKE AN EARLY KING ALFRED, NARCISSUS GOLDEN HERALD.

of cone pictures, which a month ago received a well deserved silver-gilt Grenfell medal.

NEW AND RARE PLANTS.

Arctostaphylos Manzanita.—This name will be strange to many lovers of hardy trees and shrubs, although they will be thoroughly acquainted with its near ally, *Arbutus Unedo*. In general appearance when in flower this small tree or large shrub might be described as being an *Arbutus* with the foliage of a *Eucalyptus*, but it differs from both in its brownish red, smooth fruits, though it has not been known to fruit in this country. It was introduced from California in 1897, and the specific name *Manzanita* is the old Spanish-Californian name for the Bearberries generally. A splendid vase of flowering branches was shown, and this, with the large panicles of white Lily of the Valley-like flowers slightly flushed with rosy purple, the stiff, heart-shaped, grey-green leaves and purple stems was strikingly beautiful. First-class certificate to the Director, Royal Gardens, Kew.

Primula Juliae Hector Goode.—This is the largest-flowered of the *P. Juliae* varieties, and the massed plants bearing plenty of rich purple flowers, which have velvety crimson zones and a distinct pale golden eye, were particularly effective. Shewn by Mrs. J. J. Goode.

WHAT IS A MORAINE?

IN an English gardening sense the "moraine" is a quantity of stones, watered from below, devoted to the choicest and most delicate alpine plants. The Rev. Wolley Dod thirty years ago wrote me once of an experiment he was making at Edge Hall for the culture of such things as *Eritrichium nanum*, *Ranunculus glacialis*, etc. He explained to me that he was taught by nature, having seen in the Alps how rich were the moraines in such delicate plants. This is all right and I know his results were excellent. Miss Willmott made something of the sort at Warley, where I saw our best high alpine flowering perfectly on such a construction. Later on, however, I saw so-called "moraines" made of a peat bed covered with stones. This is quite another system of growing difficult alpine—a system I have adopted here for many years. I call such an erection a "tourbière." The turf grounds and peat bogs are, indeed, the best refuges for such plants as cannot tolerate our dry and Continental climate for they are watered from below and continually give off water in the form of vapour, and the stronger the sun the greater the amount of moisture given off. Hence the "tourbière garden" system we introduced at Floraire. We built a long cemented bed 4ft. broad and 3ft. deep. At the bottom we placed, 1ft. deep, rolled stones upon which we placed a bed of moss. Over it we made a good bed of loam and peat. The bottom end has a small opening formed to allow the water, which is supplied to the bed by a little spring and runs underground, to escape. In such a bed the plants never have to be watered, and in such conditions we can grow here in our Continental climate the things you in England may grow under better conditions than we can, as your atmosphere is charged with more water than ours.

But the real "moraine," the one of the Rev. Wolley Dod, is another thing. Take for guidance as to what is a moraine the beautiful work of Professor Tyndall, "The Glaciers of the Alps," and study the matter there! It will be seen that a moraine is a mass of stones, gravel and dirt that the glacier bears on its surface and deposits at its edges and its base. These masses of *débris* which frosts and tempests throw down from the high cliffs are of different natures according to the formation of the rocks (granitic or limestone). Hence the difference of the vegetation on the different moraines.

These moraines are only sand and stones. In time the aspect of them changes, thanks to vegetation. In their lower parts they get the seeds of forest trees, and after centuries have passed timber comes to adorn and vivify them. Swiss Pines (*Pinus Cembra*), Larch and Spruce are the main species. In the higher parts the moraine adorns itself with the choicest of saxatile plants: *Linaria alpina*, *Campanula pusilla* and *CC. cenisia*, *Albionii* and *excisa*, *Androsace glacialis*, *Artemisia spicata* and *A. Mutellina*, *Achillea atrata* and *AA. moschata*, *Herba-rota* and *nana*, *Gemm reptans*, Alpine Poppies, *Edelweiss*, *Antennaria*, *Draba*, *Gentiana alpina* and *GG. Clusii*, *Kochiana*, *verna* and *brachyphylla*, *Crepises*, *Erigeron alpinus* and *E. uniflorus*, *Gypsophila repens*, *Saponaria ocyimoides* and *S. lutea*, *Helianthemum*, *Globularia cordifolia*, *Herniarias*, *Paronychias*, *Jasione*, sometime, but rarely, *Eritrichium nanum*, *Phyteuma hemisphaericum* and *P. paniculatum*, *Arabis cærulea* and *A. alpina*, *Petasites*, *Epilobium Dodonai*, *Oxytropis*, *Potentilla aurea* and *P. grandiflora*, *Primula viscosa*, *Ranunculus glacialis* and *R. alpestris*, dwarf *Salix*, *Saussurea*, *Saxifraga aizoon* and *SS. aizoides*, *muscoïdes*, *aphylla*,

cæsia, *oppositifolia*, *biflora*, *retusa*, *bryoides*, *aspera*, etc.

As will be seen, these plants are frugal species which do not like soil rich in humus. Rather

do they appreciate sandy, gritty soil. They are what we call first "colonisatrices" of the ground and like light and hungry soil.

Floraire, Geneva.

HENRY CORREYON.

A NEW EVERGREEN FLOWERING SHRUB

THAT Californian shrub or small tree, *Arctostaphylos Manzanita*, is one of the most distinct and attractive evergreens in the outdoor garden early in the year. This year and several mild winters of recent years the bushes have been very gay with blossoms during February, but in

Meehan and Sons, Germanstown, Philadelphia, U.S.A., early in 1897. The *Arctostaphylos* belongs to the Natural Order Ericaceæ, and is allied to the *Arbutus*, thriving under similar cultural conditions. In the lime-free and well drained sandy loam at Kew peat and leaf-mould are added previous to planting. Unsatisfactory results obtained in germinating imported seeds suggest that exposure to frost, steeping in boiling water for a few seconds, or subjecting the seeds to fire-heat are desirable to penetrate the hard seed-coat formed through ripening in hot, dry regions. Failing seeds, I see no reason, why grafting should not be a successful means of propagation, using *Arbutus Unedo* as the stock. The hard and smooth nature of the wood does not lend itself to increase by cuttings or layering, at least we have so far failed in these respects, but it is a field for further experiment both as to the season for such work and the nature of growth selected. Transplanting is not an easy matter, and we find it best to grow the plants in pots until large enough or the position is ready for the permanent planting.

When exhibited by the Director of the Royal Botanic Gardens, Kew, at the R.H.S. meeting

THE SPLENDID BEARBERRY, *ARCTOSTAPHYLOS MANZANITA*.

normal winters of frost and snow, March and April is the usual season of flowering. As, however, the flower-buds are formed by the autumn, there is always a certain amount of interest during the winter in watching the progress of their gradual development.

The common or popular name of *Manzanita* is used for all the members of the genus in California, but it is used in particular for the subject of this note, which is undoubtedly the most beautiful member of the family.

Travellers describe the native bushes as sprawling shrubs, varying considerably in height from 1ft. or 2ft. at high elevations to 20ft. to 25ft. in good soil at lower altitudes, with a trunk 10ft. or 12ft. in girth, and a spreading head of considerable dimensions. Under cultivation it forms a wide spreading shrub up to 10ft. in height at Kew and as much in diameter. The largest plants were raised from seeds obtained from Messrs. Thomas

on February 27 this fine evergreen shrub received a first-class certificate.

The thick, leathery leaves vary in shape from ovate to oval, 1½ins. to 3ins. long and 1in. to 2½ins. wide, entire and grey-green in colour. The flowers are freely produced in short terminal panicles, the individual blossoms pitcher-shaped, about ½in. long. Seen at a distance the colour, as seen in the hall, appeared to be white; but on the bushes the flowers are flushed with pink. No doubt in pure country air the flushing would be more prominent than at Kew. Other notable features of the bushes are the shining dark red younger branches and leaf-stalks, and the red bark of the stems, which flakes off in spring.

Had the flowers been removed from the cut sprays seen in the hall the stems and leaves might very easily have been mistaken for those of some *Eucalyptus*.

A. O.

TOWN GARDENS

GARDENS in the country are not so very wonderful, although one may sometimes be surprised at the wasted opportunities to be seen in them; but gardens in towns, big, sprawling, smoke-enveloped cities, are another thing altogether.

Nearly everyone loves flowers, although probably most of us would think a lot more of them if we understood only a small part of their wonderful complexity of form and the way in which their every part is essential to the rest of the plant and has its definite work to do. It is human nature to value most that which costs us the most in time and trouble, and it is more than likely that as much pleasure will be derived from the small town garden as from the more easily made country one.

Yet even if the town garden is small and enclosed and smoky, it may be made surprisingly beautiful, and often in a way that even the size of a country garden might make impossible.

To begin with, a small garden must have definite form. Its enclosing walls, the borders and paving all must be in harmony with and proportional to the size of the house. Walls and boundaries are generally existing, and one has to cover them with climbing or other plants; but the ground, probably an uninteresting combination of dank-looking borders and dirty gravel paths, will almost certainly call for treatment. After the borders are marked out and replenished with fresh loamy soil the rest of the space should be paved with York stone or red brick or whatever is most in character with the architecture of the house.

Paving must be carefully fitted and laid, and except for a slight fall to the most suitable spot, it must be level. It is an erroneous idea that in order to be beautiful, walls and pillars must look as if they are falling down, and paving be uneven and offer traps and pitfalls for the unwary.

Having seen to the walls, the next thing is the paving (never use cement or concrete for this). Although paving costs a certain amount to start with, it is really economical in the long run, and it has many advantages. It is dry even quite soon after a shower, and its colour, especially just after rain, can be very beautiful; besides, it is there for always, and one can make a home for some plant in every crack and crevice in a way impossible with a gravel walk, for one could not possibly cover the gravel walks with *Thymus* or dwarf *Campanulas*, or the gardeners, if there were any, would probably give notice in a body.

In a town garden, once it is made and planted, it might not matter so very much if the gardener or gardeners did go, for in a small, properly made garden there is really very little work, and that little very much a pleasure to do. It is always advisable to have the garden properly designed, made and planted to start with, and afterwards there will probably be little trouble.

But a garden, even in London, must, if it is a garden at all, have plants, and it should be filled with them, the walls should be covered, borders filled, and boxes, tubs and vases all be made to add to the beauty of the scene. There are numbers of climbing plants for the walls. Vines do well in London, and the ornamental ones, *V. Thunbergii*, *V. Coccinea* and *V. armata*, all have large, handsome foliage, colouring well in autumn; while *V. purpurea*, although not so large, is purple all through the summer.

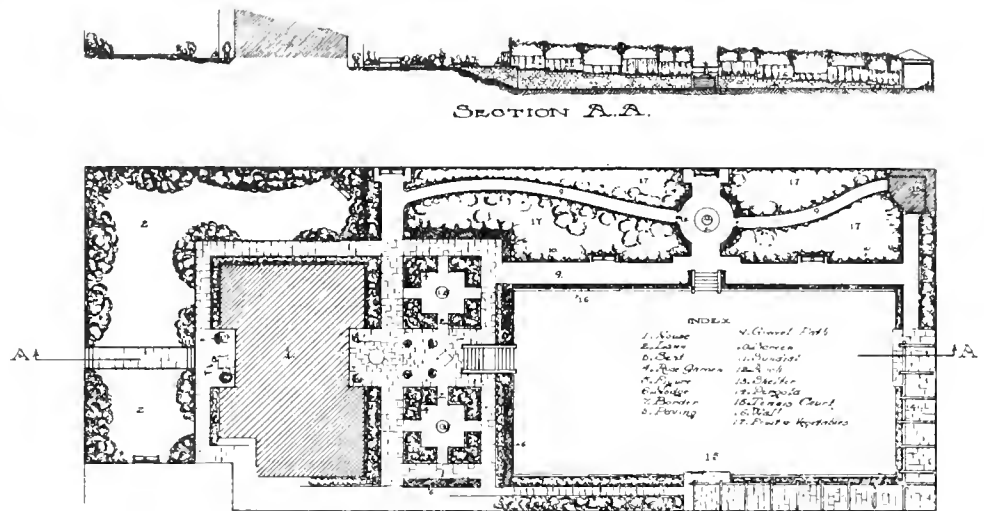

To begin to make a London garden is something like starting on a voyage of discovery. One is never quite sure what plants are going to thrive and what will gradually wither and die. There are unexpected pleasures, and, as well, there are

disappointments. The pleasures, nevertheless, far outweigh the disappointments, and if one is artist enough to use or to appreciate the use of all materials—bricks, stone, timber, plants—as they should be used, everything subservient to and helping to make the finished whole, then one may have tremendous and mending pleasure from the results of one's thought and work.

Proportion is the essential factor in all good design, and this applies equally to planting as to the actual constructional work of the garden. The plants must be to scale, and very strong-

most suitable Roses, such as Dorothy Perkins, Lady Grey, etc., and treat them as ordinary climbing Roses, that is, to grow them to the top of the walls and treillage, etc., and then let them hang down as they like. They will probably grow and flower more freely for being higher up, and it is at the top of the walls they will be most effective.

As regards backgrounds, the colour value of some dirty old walls is wonderful. They can, it one likes, be covered with treillage, and the treillage can be an essential part of the design of the garden, or the climbing plants may be nailed to the walls. Treillage can, however, be a very effective part of the treatment of a town garden. It can be used

A NEAT TOWN GARDEN PLAN.

growing ones must be kept out of a tiny garden. Fortunately, the number and variety of plants from which to choose is so great that one can have what one likes for small or larger gardens.

Unless the garden is very enclosed, there are many plants that will stand permanently even the London atmosphere, although I do not think as a rule it is so much the atmosphere as want of sunlight and air that are the greatest enemies to plant life in large towns. Nearly all bulbs are safe for a season, and some for longer. The hardier Ferns will most of them do well, and among them in a shady border may be planted the varieties of *Lilium tigrinum*, the glowing orange scarlets of which are very effective against the dark green Fern fronds.

Lupins do well almost anywhere, especially the blue and white herbaceous ones, and the rose-coloured ones will succeed under fairly favourable conditions. Delphiniums, again, are valuable as permanent residents, but only the well known older sorts of proved constitution should be planted. The stately spikes and beautiful colours of these handsome plants will give tone to any border.

To return for a moment to what I will call the constructional work of the garden, if possible have some little dwarf walls in it somewhere; they can generally be arranged across an end of the garden or, perhaps in a corner. They should be coped with York stone and built just high enough to sit on. They will make handy seats, but one must have cushions or something else to put on them. They are also excellent for standing bowls and pots upon, in which may be grown some especially valued plants.

Roses, Clematises and other flowering plants should be planted to grow over and among the Vines and Ivies that clothe the walls, for the sake of the colours of their flowers. It is a good idea to plant weeping standards of some of the

to block out unsightly corners, and it is easier to train growing plants to it than to nail them on to walls; also the effects of light and shade are much richer because of the extra depth of shadow.

It is well to have good clumps of the permanent residents in the garden, and to fill in annually with groups of plants that may be relied upon to give plenty of colour through the summer and to stand the London atmosphere. Other plants that will stand the confined town conditions are Hollyhocks, some of the stronger-growing Chinese *Pæonies*, *Antirrhinums*, the invaluable Catmint (*Nepeta Mussini*), the different varieties of *Chrysanthemum maximum*, *Alkanet* (*Anchusa*) and most of the perennial *Asters* (*Michaelmas Daisies*).

In a small town garden it is an easy and a comparatively inexpensive matter to keep the borders full of plants and colour for eight or nine months of the year, from early spring until the first severe frosts spoil the later blooms of Dahlias and outdoor *Chrysanthemums*.

For the summer, after the early bulbs and other spring-flowering plants have been cleared away, the spaces left should be filled with *Begonias*, *Geraniums* (the Ivy-leaf sorts stand shade better than Henry Jacoby and Paul Crampel), *Marguerites*, of which the double one is the nicest; *Heliotropes*, which, like *Begonias*, rather like a certain amount of shade; and in some places *Verbenas*. *Fuchsias* are most accommodating, and can be grown on in pots from year to year into quite large plants, as they need little attention during the winter beyond being stored in some frost-proof shed or outbuilding and an occasional watering.

Young plants of hardy annuals, such as *Giant Comet* and *Ostrich Plume Asters*, may be planted in sunny spots; but, for London, plants such as *Zonal* and *Ivy-leaved Pelargoniums*, that may be planted just as they are beginning to flower, will generally give far better results than those

that have to grow and flower later. Pentstemons do not do well in enclosed places; they grow too high and do not flower freely, but Pansies and the different strains of Violas may all be planted freely.

No opportunity should be lost in London of carrying one's garden as far up the walls as possible. Walls, balconies, window-boxes should all be covered or filled with growth, and flowers of plants and creepers, Pentstemons and Ivy-leaf Geraniums can hang their graceful sprays from window-box and hanging basket so that the eye is carried upward by the continuity of colour, and pottery and vases also filled with one's favourite flowers can stand about on walls and paving, giving, if they are well chosen, just the finishing touch to the garden.

Do not forget that in a town garden the paving itself is a garden, and every joint and crevice can be planted with some dwarf plant. See that the paving is in rather big pieces, so that there is plenty of room to walk about without treading on the plants, and Thymes, Alyssum, Aubrietia, Thrifts, Menthas and Arenaria can fill every line and joint and add greatly to the beauty of the garden.

There is very much of both health and pleasure to be derived from the making and care of a town garden, and for those who are kept much in town it will add greatly to the pleasure of life to have even a small garden wherein, even in the heart of a great city, they can be amid the flowers.

PERCY S. CANE.

CORRESPONDENCE

THE HARDEST SCHIZANTHUS.

HAVE fellow gardeners in England found out how much harder the dwarf *Schizanthus wisetonensis* is than the typical *S. papilionaceus*? After several years of trial I have never known it suffer materially from the worst frost or bad weather on this coast, and I feel pretty sure it would succeed in the South of England if grown in cold frames that were never closed down tight at night or shut up at all, save in the worst weather. Its charmingly cut green foliage and stocky growth would make a very useful contrast to the flowering bulbs and Polyanthus of English gardens. Here it begins to flower in January, but the end of March would be early enough for England, while its dainty pink or white flowers continue for two

it he says that the ample material sent him last autumn agrees with the only English specimen he had previously seen, and confirms his belief that "the *C. eriophorum* that occurs in England is certainly different from the forms found on the Continent; a good race and easily distinguishable by the structure of the scales of the involucre and the size and shape of the flower-heads." Dr. Petrak's Monograph on the genus *Cirsium* is not yet published, it having been delayed by the war.—H. S. THOMPSON.

A BEAUTIFUL CODONOPSIS.

I HAVE often wondered why that beautiful Bell-flower, *Codonopsis ovata*, is not more grown in gardens. Its flowers are interesting as well

belonging to the main genus. *Codonopsis ovata* is certainly a beautiful plant—it is illustrated herewith—and so far as we are aware it is of the easiest culture. It is certainly so on light soils. Perhaps other readers will give us their impressions of the plant's needs and the reason for its comparative unpopularity.—ED.]

TWO CAPITATA PRIMULAS.

HAVING cultivated that lovely species *Primula sphærocephala* for a few years, I was very pleased indeed to see it brought to public notice in THE GARDEN on February 3. This charming *Primula* was collected in the Kari Pass, Yunnan, by G. Forrest and introduced to cultivation by Bees, Limited, in 1908. It is still rare in gardens. Why I do not know, for it is easily procured and not difficult to cultivate; in fact, it will flourish in ordinary soil, but prefers a good loamy soil with leaf-mould and sand added. It requires a fair amount of moisture and moderate shade to get it to perfection. I consider *P. sphærocephala* one of the most beautiful of the smaller Chinese species yet introduced. Moreover, it is quite perennial, although, to keep up vigorous plants, seed must be sown every other year. The flowers are of a purple-blue shade sprinkled with silver meal. Some writer aptly described it as resembling a bunch of violets that has been dipped in the flour bag. *P. sphærocephala* is closely related to the Indian species *P. capitata*, but the difference is readily noticed when they are seen growing side by side. *P. pseudocapitata* is another fine Chinese *Primula* of the same group. We owe its introduction also to Bees, Limited, and to Kingdon Ward, who collected the seed in North-West Yunnan in 1911. *P. pseudocapitata* is quite hardy and a grand companion to *P. sphærocephala*. It makes a grand show when planted out in large groups and enjoys the same soil and position as recommended for the already mentioned species. The flower-heads are rather flat and quite distinct from the other species. Several of my friends seeing *P. pseudocapitata* for the first time have remarked, "Is this a new *Scabious*?" The flowers are purple but smaller than any of the other *Primulas* of the same section. These charming Chinese *Primulas* and many others are admirably grown by Messrs. Oliver and Hunter, nurserymen, of Moniaive, Dumfriesshire, where, towards the end of last summer, I had the pleasure of seeing two lovely forms selected, one from each species under notice. The plants are more robust in every way, the flowers larger and of a darker shade than the types. If these improved forms come true from seed, they ought to prove a welcome addition to our gardens.—WANDERING SCOT.

FRAGRANT FOLIAGE.

AMONG old-fashioned plants in country gardens one still comes across on rare occasions collections that are valued, not so much for the blossoms they bear, but for the pungency of their leaves. One has but to mention Rosemary and Lavender, Myrtles and Sweet Briars, bushes of which are allowed to go from year to year until they assume large proportions, and in not a few instances appear to have become, like the trim Box edgings skirting the paths, part and parcel of the homestead. I venture to say that there are readers of this note who have a recollection of the time when scented-leaved plants like Bergamot and Baln of Gilead (*Cedronella*) and Old Man (*Artemisia Abrotanum*) occupied places in certain gardens years ago. Who to-day considers them fit for planting in a border much less holds them suitable for cutting for a bouquet? Yet our grandfathers did! In the greenhouse too, in former days the Lemon-scented Verbena (*Aloysia citrodora*) had its allotted space, and

A NEAR RELATIVE OF THE CAMPANULAS, CODONOPSIS OVATA.

months or more. It is a most useful and enduring annual.—E. H. W., *Nuc.*

AN ENGLISH THISTLE.

IN my illustrated note on that handsome Thistle, *Cirsium eriophorum* (October 28, 1922), it was briefly stated that Dr. Petrak of Czecho-Slovakia calls the English form sub-sp. *anglicum*. A second letter from him has at last arrived. In

as beautiful, and its bluish-mauve colouring is attractive. On my light, warm, sandy loam I have never found any difficulty with it, either in full sun or in semi-shade. It is a good perennial also, yet it seems little grown. Can someone tell me why?—S. S. Warwickshire.

We might hazard a guess that there are so many fine Campanulas that gardeners usually overlook other Campanulaceous plants not

the highly perfumed Stag's Horn Pelargonium was grown as a matter of course. In my youth I remember a greenhouse where a number of "scented-leaved Geraniums" was grown, including an almond perfumed sort known as Pretty Polly. It is the exception to meet with such plants in these days, and, like some of the fancy-leaved sorts, such as Mrs. Pollock, Beauty of Lauderdale, Lady Cullum and Her Majesty, they are fast dying out. We hear numerous complaints as to the lack of scent in Musk, and there is something in the assertions, but certainly the small-leaved variety which at one time had

it comes to perfection outdoors. It is still grown for market.—CLAREMONT.

CROCUS CLOTH OF SILVER.

CROCUS CLOTH OF SILVER, which is a form of *C. biflorus*, is valuable because, like the early-flowering yellow Dutch Crocuses—forms of *Crocus aureus*—it is early flowering. There are, of course, beautiful white forms of *Crocus vernus*, but these usher in the Daffodils. Late flowering may be forgiven to the glorious purple Crocuses, but when the Narcissi bloom there is little scope for other flowers of white or

positions, towards the back of a rockery where a tree gave partial shade but also tended to draw the growths unnecessarily, and on a sloping bank, which position gave to the foliage a somewhat hardened and bronzy look rather than a withered appearance as mentioned in the note referred to. In neither site was winter protection given. Of course, one of the best, perhaps the best, of the Rues is *Thalictrum dipterocarpum* with a violet or purplish inflorescence, the only species, I believe, that has gained the award of merit of the Royal Horticultural Society.—C. T.

I HAVE plants of this passing through their ninth winter here without any protection whatever beyond what is afforded by their own dead foliage. We are 500ft. up, exposed to all winds, with a clay subsoil, the land around here being very damp in winter. From sunrise to noon the plants get every ray of sunlight, after that the shadow of the house is upon them, except in summer, when they enjoy an hour or so of sun down the passage between this house and the next, and that frequently makes their position draughty. Also they get all the east and north-east winds. I therefore consider it perfectly hardy.—ALAN HIBBERT, *High Lane, near Stockport.*

HAVING grown *Thalictrum adiantifolium* for a number of years in a Northumberland garden. I can speak of its hardiness. Several plants were in a border partly shaded by a large *Araucaria imbricata*. These did well each year, although they had no protection during the winter. The soil in which they were growing was well drained and had a good deal of lime-rubble mixed with it, also leaf-mould.—C. L. CAWELL, *Yorks.*

DAPHNE BLAGAYANA.

THE genus *Daphne* provides us with some of the choicest of spring-flowering shrubs. Its delicious perfume appeals to all. *Daphne Mezereum* is one of the best known of the genus, and its leafless stems covered with crimson-purple flowers are very frequently seen in gardens before the snows have disappeared from the hilltops, and its delightful fragrance can easily be felt some distance away. *Daphne Blagayana* is quite a different type of plant. Instead of growing erect like the *Mezereum*, its growth is straggly and evergreen, spreading itself along the surface of the ground. It is seen to advantage in the rockery, where its long, slender shoots wind in and out among the boulders. The flowers, which are produced in terminal clusters on the previous year's shoots, are creamy white and deliciously fragrant. It is a pity this choice little shrub is not more frequently grown; it is quite hardy and not at all difficult to grow. One of the finest plants we have seen is in the interesting rock garden at Ochilview, near Perth.—ALBYN.

A FAIRY CROCUS.

CROCUS *ÆRIUS* has been well called a "fairy Crocus," as it is a gem among the many jewels which constitute the family. It is, unfortunately, not always long-lived, and in northern gardens has not generally proved so satisfactory as many of the race. It is difficult to describe all the lovely tones of blue or lilac it affords us, and these are so delicately shaded and combined that a group of flowers will well repay some study and will afford endless delight when in bloom and open to the sun. The charming featherings immensely increase the pleasure it affords. *C. ærius* is one of the early-blooming Crocuses, and should be represented in all good collections of these fascinating flowers, even deserving the shelter of a frame where it is not so long-lived as we would like.—S. ARNOTT.

A CLUMP OF CROCUS CLOTH OF SILVER.

its place in many a cottage window possessed fragrance both in flowers and foliage.—W. LINDERS LEA.

[It had not occurred to the Editor that Lavender, Rosemary, Sweet Briar or Old Man were going out. He would rather have said that they were being planted to a much greater extent now than they were two decades ago. Quite a collection of *Artemisia* is now grown because of the silvery beauty of the foliage.—ED.]

AN OLD FAVOURITE.

IT is questionable whether there are many Chrysanthemums grown to-day—if any—that were contemporary when *Source d'Or* was introduced in the early 'eighties, and the explanation why this has survived the years when so many beautiful sorts have gone out of existence is to be found in its colour—old gold. It is well known that size of bloom was a great factor (and is, indeed, to-day) in the matter of exhibition blossoms, and whatever other qualification a variety possessed, little regard was paid to it if it fell short of the monstrosity. *Source d'Or*, however, because of its delightful colour, although it has long since been relegated to the decorative section, has never really been superseded, even if it has been improved upon at all, and there are growers of Chrysanthemums for home decoration to-day who hold this sort in much esteem. It is an early mid-season variety, right for blooming in a cool house, needing little or no artificial heat; indeed, in favourable seasons

yellow colouring I was glad to see the article on Crocuses. Few gardeners have any idea of the number of varieties or their charm.—S. D.

"ROCK GARDEN" IN EMBANKMENT GARDENS.

I NOTE that in the Embankment Gardens just on the east side of Charing Cross Station the L.C.C. have recently erected a continuous row of large blocks of apparently manufactured yellow sandstone in two or three tiers and about 80yds. long, facing due east and north, with a row of trees immediately behind (on the west side). It would be interesting to have your views on this arrangement, both from a practical and artistic point of view.—MORGAN WILLIAMS.

[The Editor has visited the site and thinks from a practical point of view the arrangement should answer well enough. There is, unfortunately, nothing artistic about the spot in question. The "rock-work" will add little to its amenities and is, from our point of view, a waste of ratepayers' money. The introduction of supposedly natural features, however well done, into the narrow spaces between lofty town buildings offends present-day taste. It is a Victorian survival.—ED.]

THALICTRUM ADIANTIFOLIUM AND ITS HARDINESS.

RE the note concerning the above subject, page 48, January 27 issue, my experience confirms that of the Editor, that this Rue is quite hardy. In a former garden we grew this plant in two

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Carrots.—A few lines of a stump-rooted variety may be sown, but the intermediate or long kinds are best left for a time, until the ground becomes warm and the weather congenial. The seeds should be just covered with fine soil. Carrots enjoy a deeply dug piece of ground without manure. An occasional sprinkling of soot should be given where the carrot fly is likely to appear.

Cauliflowers.—Plants that have passed the winter in handlights or cold frames should be transferred to their final quarters. The ground must be in good heart, and a liberal dressing of partly rotten manure is essential to produce plants of first-class quality.

Cabbages.—There are excellent varieties available for sowing at this period, and this crop usually comes in very useful. A sowing of Red Cabbage can also be made if pickles are appreciated.

Brussels Sprouts.—Seeds should be sown in drills 1 ft. apart to produce a later supply of sprouts. Broccoli should also be sown for autumn use, and the same remark applies to Cauliflowers of the Autumn Giant type.

Spinach.—Where this is in frequent demand an occasional sowing is necessary, and it is a very good plan to sow a line between two rows of Peas, the Spinach reaching maturity before the latter are too far advanced. The Perpetual or Spinach Beet should also be sown in rows 18 ins. apart as it will be found useful when the summer variety is not available and, moreover, it is productive for a long period.

Celery.—Seeds should be sown for the main crop, choosing both a red and white variety. Sow in boxes of light soil and place them in a warm greenhouse or on a mild hot-bed until germination takes place.

The Flower Garden.

Roses.—During the present month the plants in the rose garden and other parts may be pruned. Secateurs are often used, but wherever possible a sharp knife should be employed. All the spindly and unripe wood must be removed, leaving the strong, healthy shoots of last season to furnish the growth this year. These shoots should be cut back as a rule to one-third of their length, but varieties differ so in habit that the pruner must use his own discretion to a large extent. The weaker-growing varieties may be pruned back to two or three eyes, and standards of almost any kind may also be pruned back. With some of the strong-growing sorts the growths can be pegged down, leaving the shoots nearly to their full extent. Polyantha Roses should be thinned and cut back, but most of the single type, such as Irish Elegance, are best left to grow more or less naturally.

Violas.—Cuttings that were inserted last autumn in frames or in the reserve garden may be transferred to their flowering quarters. They are very effective in almost any position, but especially as an edging to Rose-beds. V. Maggie Mott is excellent for this purpose.

Fruit Under Glass.

Late Vines.—It is time the late vinery was started, and at the commencement, a night temperature of 50° will be ample, with a rise of 10° or so during the day. The border should have a little of the top soil removed, providing it can be done without injury to the roots, and then replaced with a liberal sprinkling of bone-meal and fresh fibrous loam. Where the border is outside it should be covered with partly rotten manure and leaves. Keep the floors and stages damp, and, when growth is apparent, raise the night temperature 10°.

Vines.—In the earlier houses disbudding and tying down will need attention, and the pinching of the shoots two leaves beyond the bunch will be necessary. The number of bunches must be reduced at an early stage so as not to overcrop the Vines. In some houses the thinning of the berries will be in progress, and such work is always best carried out before the bunch becomes tight. Care must be exercised when thinning Grapes. Sharp scissors are essential, and the operator ought not to handle the bunch or rub it with his hand. All unfertilised berries must be removed, and at the final thinning the natural size of the berry must be taken into consideration.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Early Potatoes.—No time should now be lost in getting these planted if the soil be in good working order. A south border is an ideal place for them; 2 ft. between the drills is sufficient for the earliest, with 1 ft. between the tubers in the drill. I prefer a drill formed by means of the draw hoe to any of the other methods of planting. By this method the drills are drawn expeditiously and are of uniform depth, and the covering is done by the feet, leaving the soil in a loose condition.

Parsnips.—Sow seed thinly in shallow drills about 10 ins. apart on ground that has been deeply dug and to which no rank manure has been applied. The Student and Hollow Crown are excellent varieties.

Savoy.—Sow seed of an early variety, such as Early Elm, for autumn supply, and Ormskirk for winter and spring supply. As far as I know, this excellent variety has no rival as a spring Savoy.

Borecole or **Kale** is a very useful winter vegetable, and is less fastidious as to soil and situation than most others. Sow now. Dwarf Green Curled and Dobbie's Exhibition are reliable varieties.

The Hardy Fruit Garden.

Black Currants.—Those who are troubled with the mite should take steps to combat this pest throughout this and next month—the period of migration. Equal parts of quicklime and flowers of sulphur should be applied to the bushes about every ten days, either in the dry state with a dredger or wet with a syringe or sprayer.

Strawberries.—Runners which were taken in autumn and wintered in nursery lines should now be planted in deeply worked soil that has been moderately enriched. Plant in lines from 24 ins. to 30 ins. apart, according to the vigour of the variety. Allow 18 ins. between the plants in the line. Light vegetable crops may be grown between the lines the first season, or Wallflowers and other biennials can be sown in the spaces and be planted in nursery lines in due course.

Fruits Under Glass.

Figs in pots or tubs should be assisted with occasional weak applications of liquid manure. As trees with a more extended root-run begin to make young wood, sufficient of it should be retained, but all superfluous shoots should be cut away at an early stage.

Early Vines as they come into flower should be given a rather drier and more buoyant atmosphere and the temperature slightly raised, a night temperature of 60° for Hamburgs and 65° for Muscats being about right.

Strawberries.—Give bi-weekly applications of weak liquid manure until the fruit begins to colour. Expose to full light.

The Flower Garden.

Antirrhinums.—As soon as the seedlings have developed the first pair of true leaves prick them off into boxes of light soil and keep them in their present quarters till they have again taken root, when they should be hardened off in a cold frame.

East Lothian Stocks.—Prick off into boxes those that were sown in January. Run the Dutch hoe occasionally among those that were planted out in autumn for early summer display.

Half-Hardy Annuals.—Sow in gentle heat Ten week Stocks, Dianthus Heddergii, Nemesis strumosa and compacta, Phlox Drummondii, Salpiglossis and Zinnias.

Auriculas and Polyanthuses.—Make a sowing of these now in gentle heat for flowering next season. Seedlings are superior to stock raised by division. Some firms offer fine classified strains of Auriculas: the yellows and helios are especially attractive. Polyanthus seed can also be had in strains of yellow, white and red.

Gladioli.—If any portion of the stock is wanted to flower early, the corms should be potted singly into 3½ in. pots and started into growth in a vinery or peach-house.

The Pleasure Grounds.

Grass Edgings should be trimmed with the edging iron while they are in a moist condition. Except on narrow verges, the roller should be run along before commencing to pare them. Take off as little as possible consistent with straightening the whole.

CHARLES COMFORT

(Formerly Head-gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Greenhouse Walls.—Many conservatories and greenhouses are built up against walls. Such walls are ideal for training quite a variety of plants on, especially if there is nothing much in front to obstruct light. There must be, of course, facilities for constructing a suitable border at the bottom of the wall. This border need not be wide, 18 ins. to 2 ft. being quite wide enough to grow most plants. The border should be about 2½ ft. deep and well drained. A few good plants for such a wall are Soliva heterophylla, Lathyrus pubescens and L. splendens, Camellias and Oranges, which can be pruned and trained in much the same way as Peach trees. Some of the stronger-growing Abutilons are very suitable for this purpose, also Luculia gratissima, Tibouchina semidecandra (perhaps better known as Pleroma cranthum), Chorizema ilicifolium, Cestrum elegans, C. Newellii and C. aurantium, and Pentapterygium serpens. There are also several strong-growing Begonias which are seen at their best when grown in this way, viz., B. fuchsoides, B. coccinea, B. Luzerna and B. President Carnot. There are, of course, many more plants suitable for this purpose, and the above may be some guide to the intending planter.

Malva capensis and **M. coccinea** are both very neat-growing plants with a stiff bushy habit which are useful for the greenhouse during the summer months, as they remain in flower for quite a long time. They are easily propagated by means of cuttings at any time, but now is the most suitable time to work up a stock of plants for next year. They root readily in a close case with slight bottom-heat and grow quite well in a cool greenhouse.

Malvastrum hypomadarum is similar to the Malvas, but has larger and more showy flowers, is a much laxer-growing plant, and requires frequent stopping to induce a bushy habit. This plant is really seen at its best when it can be planted out and trained up a sunny wall in a cool greenhouse; otherwise it requires the treatment indicated for Malva capensis.

Veronica Hulkeana is, when well grown, a beautiful plant for pot cultivation, although by no means an easy plant to do well. It should be given perfectly cool treatment at all times, or else it grows weak and weedy. It may be propagated at this time by means of cuttings, which should be inserted in a cool case. The young plants should be stopped several times to induce a bushy habit. In their first year they make good plants for furnishing the stages. If grown on for two years they make fine large specimens 3 ft. to 4 ft. high, but such specimens require a good deal of care to bring them to perfection.

Veronica speciosa, of which there are many beautiful varieties, although more or less hardy in the South and West, is very useful for furnishing the cool greenhouse, especially during the autumn. If young plants are rooted at this season, they make nice plants in 48-sized pots by the autumn, and may be grown in cold frames during the summer. Plants grown in this way last year may now be potted on into 6 in. or 7 in. pots, and will make fine large specimens by autumn.

Veronica diosmifolia is a very pretty compact-growing species which flowers with wonderful freedom during the spring. It is easily propagated by means of cuttings, and does not require any stopping as it naturally makes a small compact rounded bush. It requires quite cool greenhouse treatment at all stages of its cultivation.

Chenostoma hispidum.—This South African plant produces its white flowers very freely, and is very useful for furnishing the greenhouse during the autumn. A stock of plants may be raised by means of cuttings. They root quite readily in a close case with slight bottom-heat. The plant is naturally free branching and compact, and does not require pinching. During the summer months it may be grown in a cool house or a cold frame.

Streptosolen Jamesoni.—Plants raised last year, and now in 6 in. pots, should be potted on until they are in 10 in. or 12 in. pots, in which they make fine specimens for the conservatory. To ensure freedom of flowering this plant must have full exposure to the sun, and is seen at its best if it can be planted out and trained on a warm, sunny wall in the greenhouse with full exposure to sun and light. The flowers are orange-scarlet, and a good plant in full flower is very gorgeous. It is easily propagated by means of cuttings during the spring.

THE BRITISH EMPIRE EXHIBITION

We have received the following from Mr. Wm. Watson, Secretary of the Horticultural Committee of the above Exhibition:

IT was clearly evident at the two meetings of horticultural traders held recently in London, one at the Board of Trade on January 30, the other at the hall of the Royal Horticultural Society on the 13th ult., that the great purpose of the British Empire Exhibition to be held at Wembley Park in 1924 is not grasped. The Exhibition was "designed to furnish a display of the natural resources of the various countries within the Empire and the activities, industrial and social, of their peoples." At Wembley Park arrangements are being made on a scale which will enable this to be done. The resources of every part will be mutually displayed there. Producers will find markets, markets will find producers. Sufficient progress has been made already to satisfy the management of the Exhibition that the whole Empire, commercially speaking, will be at Wembley. Our Overseas Dominions, Colonies and Dependencies are preparing for a display of their products to an extent that has already exceeded all expectations. There is every prospect that this Exhibition will surpass all others ever held in this country in magnitude and interest, and that it will afford opportunities for trade development that have never before been attempted.

So much for the Exhibition generally. Let us now consider how the project should appeal to horticulturists and to the horticultural trade generally. Preparations are being made on an elaborate scale which will afford exhibitors in every department of the industry a splendid chance of demonstrating how the United Kingdom stands with respect to horticulture. That it occupies an important position among the great industries of the country is abundantly evident. Have we sufficient enterprise to seize the great opportunity which the Exhibition will afford to inform the world what horticulture means to us, what our breeders and growers are in a position to supply? The object of the Exhibition is to enable them to do this on a scale that has never been attempted before. At the great International Exhibition held in Hyde Park in 1851 horticulture was scarcely represented, notwithstanding the fact that Sir Joseph Paxton was on the executive. No such oversight will take place at Wembley in 1924 if the facilities provided there at very considerable outlay by the Exhibition management are made adequate use of.

The Horticultural Committee is composed of sixteen representative men, Mr. William Cuthbertson being chairman, and potential exhibitors may rest assured that the efforts of this Committee are on very commendable lines. A Sub-Committee looks after the interests of sundriesmen, including horticultural builders, machine makers and engineers, and it is intended to appoint a Press Committee for publicity purposes. A hundred leading men, including amateurs, traders and scientific workers in horticulture, have accepted an invitation to form a Horticultural Council, with Lord Lambourne as president.

Although the Royal Horticultural Society does not appear to be willing to hold the May Exhibition in 1924 at Wembley instead of at Chelsea, we are assured that the Society has the interests of the British Empire Exhibition at heart and that the Council intends to take an active part in the efforts being put forward to make horticulture at Wembley a big success. This is as it should be, and we hope that other societies will also co-operate in the same

spirit. The permanent features, such as formal and rock gardens, the beds and borders of shrubs, Roses, hardy herbaceous perennials, etc., will be additional to the special exhibitions which the management desire to hold at Wembley. It is also hoped to provide exhibits of growing fruit trees showing correct method of planting, pruning and training, and plots of vegetables under the control of expert cultivators.

Another unique feature will be provided by India, the Dominions and Dependencies, which intend to have gardens furnished with striking decoration and economic plants representative of their vegetation and their agri-horticultural industries. These gardens will occupy areas adjoining the exhibition halls of the respective Dominions, etc., and should be of considerable attraction and interest. The plants for this are being specially prepared in their overseas homes, and they will be supplemented with others obtained from nurserymen in this country.

The circular letter sent out to exhibitors gives full particulars as to the lay-out of the Horticultural Section at Wembley, which will occupy about 10 acres in a favourable position with respect to accessibility and the grounds generally. Considering the period of the Exhibition, from April to October, the charges for space are not excessive. Special shows would be held in large marquees erected on a site adjoining the Horticultural Section. The profits made by societies when their shows were held elsewhere will be guaranteed by the Exhibition authorities. Some nurserymen have notified their intention to maintain a running display of indoor plants in specially erected greenhouses. In conclusion, I feel certain that if British horticulturists make the best of the opportunities which this great Exhibition will provide, horticulture will be the greatest attraction of the many that will be set up at Wembley.

ABOUT DAMPING OFF

IN the case of young seedlings this is sometimes caused by fungus in the soil, especially if leaf-mould which has not been thoroughly exposed to the air is used. When one has the privilege, as I once had, of getting any desirable quantity ready made from hollow places in the woods, where it had been thoroughly aerated by the action of birds, there is not much danger. Naturally-made leaf-mould like this is very valuable; but that which is collected and remains undisturbed in a heap till wanted is a very different thing. When there is any suspicion of fungus it is well partly to sterilise it by making it too hot to bear one's hands in. If a small quantity only is wanted, it may be placed in an old saucepan over a fire and kept stirred for a short time till it is equally heated throughout. But even after this precaution there is a liability for seedlings to damp off if the atmospheric conditions are not suitable. Great fluctuations of temperature will cause it. One may have a bright, sunny day which will raise the mercury in the thermometer to a considerable height, and a high temperature means a large amount of moisture suspended in the atmosphere.

One closes the house in the afternoon to bottle up the sun-heat, and as the heat declines the surplus moisture is deposited on the coolest surfaces, whether these be stone, metal, soil or the leaves of the plants. Large, vigorous-growing plants may not shew any ill-effects, but supposing the temperature of the house declines 20° or more during the night and the sun comes out brightly in the morning, the dew will have collected on the cold soil just at the base of the little plantlets, and will remain there till the soil becomes warm,

which in winter and early spring may take some hours. During this time I imagine the plants will feel something like I should do with my feet in cold water and the rest of my body in a summer temperature. Like the stronger plants, I might be able to bear the torture for a time, but it would be rather trying for a newly-born babe, and there is every reason to believe that plants are more sensitive than animals.

Plants also have their language, an inaudible but visible one, and only partly understood by a comparatively few devotees. The old-fashioned language of flowers is pretty, but imaginary; the language of plants is real, and gives expression to suffering and want as well as to the opposite condition. Would that I understood it sufficiently to prevent all suffering instead of waiting till the effects are visible. The leaves would not then need to turn yellow to shew they were starving or wrongly fed.

When seedlings are in pots plunged in bottom-heat or placed at a suitable distance from a heated pipe there is not much risk of damping, but if it is otherwise one may succeed in raising some early Lettuces, but Tomatoes or Stocks, if the attendant is caught napping, may give trouble.

Readers should understand that it is not always the amount of moisture in the atmosphere which causes damping. It may occur with a minimum amount of humidity, while plants in a sweet, steaming hot-bed are not likely to suffer, but it is the effect of cold water and cold soil at the base of the plant.

I have sometimes sprinkled seedlings with almost hot water in sufficient quantity to warm the surface of the soil when the morning has been bright after an unexpected frost. This was done when ventilation was given, and had the effect of relieving the plants considerably. Still, such a plan could not be repeated very often with impunity.

Damping off is not confined to seedlings; cuttings also suffer from it. Chrysanthemum cuttings, if not too soft, will live (though they may droop) and ultimately take root in a cool, draughty passage, but place them in a house or frame where they are liable to great atmospheric fluctuations and they may damp off, especially if the structure is not opened when the sun appears.

Chinese Primulas, too, are apt to suffer in the same way, and so are large double flowers, such as Chrysanthemums. It in any way one can prevent the cold water remaining on them and stagnant air surrounding them, one will most likely prevent damping.

We like to see the dewdrops on the leaves of our flowers and vegetables in the open air on a bright spring morning after a comparatively cool night. These do no harm because the air is not confined and the soil just below the surface is frequently, before sunrise, warmer than the atmosphere. But when we see or even suspect these dewdrops in houses containing flowers, fruits or tender seedlings, they should generally be taken as a danger signal.

Since penning the foregoing notes I have visited Messrs. Blackmore and Langdon's nursery and have seen their hundreds of thousands of Begonia seedlings. These are in 6in. pots and as close together as Mustard and Cress, without a shadow of damping. Mr. Langdon told me that pricking out would be started in a week's time. They are too small to handle, and I was told they would be shifted on a small stick. The pots in which the seed was sown had been placed in a propagating frame inside the house, and the most forward now had the lights removed during the day. Here, then, is the same lesson: Avoid great fluctuations of temperature during the early stages.

WM. FAYLOR.

OBITUARY

THE REV. W. WILKS.

It is with deepest regret that we have to record the sudden death of the Rev. W. Wilks. Mr. Wilks became suddenly faint on Friday morning and died almost immediately at his home at Shirley.

As every gardener knows, Mr. Wilks gave us the famous strain of Shirley Poppies; yet, great as was this triumph, his greatest achievement was, unquestionably, the work he did for the Royal Horticultural Society. He can hardly be said to have laid the foundation-stone of the Society, which had been in existence eighty-two years when he joined it; yet, without doubt, he did more to put the Society into the pre-eminent position it now occupies than anyone else.

Writing in *THE GARDEN* for May 26, 1910, this most distinguished gardener and admirable Christian gentleman wrote:

"My earliest recollections are connected with horticulture. I remember when I was only four years old my grandfather's devotion to plants, and particularly the pride which he took in the black and white grapes which he grew on a south wall in his garden at Charing, in Kent. The Rev. Joshua Dix, who was afterwards one of the leading spirits of the Royal Horticultural Society, was at that time Curate-in-charge of the Parish of Charing, and all my early remembrances are mixed up with him and Mrs. Dix (as ardent a gardener as her husband), who were most intimate friends of my family. My father was also himself a keen gardener, his particular fancy being to try all the new Pears which France was at that time pouring into this country. About 1850, Joshua Dix moved up to London, and became officially connected with the Royal Horticultural Society (his portrait now hangs in the Committee room); but his holidays were always spent in the Kent he loved so well; and to our home garden at Ashford he used to bring, or send down, all the new plants and seeds sent out by the Society. Thus from my earliest years I have been immersed in gardens, and in active touch with the inner life of the Royal Horticultural Society.

"My school life served also to intensify my love of Nature, as I was educated under that great scientist and true Christian gentleman, Professor Charles Pritchard, until I proceeded to Pembroke College, Cambridge, in the year 1861. Having taken my degree in 1864, and after a couple of years spent amongst the flowers and the open hill country of Somersetshire, I accepted the curacy of Croydon, and was again fortunate in finding in my Vicar, Canon Hodgson, another enthusiastic and practical gardener.

"Up to the time of Joshua Dix's death I was by his kindness a frequent attendant at the Royal Horticultural Society's meetings, and in 1867 was elected a Fellow, and from that day to this I have never missed any one of the meetings, save from illness or absence from home. In 1870, Archbishop Lut moved me from Croydon to Shirley, where I at once began to cultivate and improve my garden, devoting myself principally to Roses, Pears, Poppies, Peonies, Apples, Plums, Peaches, Nectarines, Dahodils, Strawberries, Rhododendrons, Flag Irises, Philæas, Tulips, Hyacinths, Hardy Ferns, Lilies, Snowdrops, and Herbaceous plants in general. About 1880 I became a member of the Floral Committee; and was elected to a seat on the Council and appointed Honorary Secretary in 1886. The Society at this time was burdened with debt and consisted of only some 1,200 Fellows, many of whom were Life Fellows whose composition money had long before been spent on costly buildings at Kennington. A resolute effort was

made by the President and Council to save the life and continuity of the Society and to bring it back to a genuinely horticultural policy, with the result that probably never before has the position of the Society been so secure as it is at the present, the number of Fellows having steadily increased up to about 4,500 and its financial balance standing at more than £8,000."

Since 1900 the Society has never looked back, and to-day there are about 18,000 Fellows. The sad tidings of the death of the Rev. W. Wilks reached us just as we were going press. In our next issue we shall refer at greater length to the life work of this devoted gardener.

EDITOR'S TABLE

The earliest outdoor Narcissi we received this year came to hand in the third week of February from Mr. W. A. Watts of the Welsh Bulb Fields, St. Asaph. These were of two varieties, Sunrise and Breda. The former is a splendid Barri variety for the garden or for cut flower. The perianth is white, with a primrose bar to each segment, and the fluted crown has a fiery scarlet margin. Breda is a useful incomparabilis with widely expanded cup, sunken and edged with orange-red. The flowers did not travel so well as Sunrise, but the perianth appears to be creamier and the flower is rather starrer in appearance. Its very informality makes it specially useful for indoor decoration.

The Crown Imperial. It cannot be said that the Crown Imperial is very popular to-day and it may be added, that where they are grown, success is not always maintained for long. In many gardens they appear to have been consigned by common consent to the shrubbery border, a position in which, not infrequently, the soil is much impoverished by the roots of trees and shrubs. To see them at their best and they rank among the quickest growing of spring-flowering plants Crown Imperials are never better served than when the bulbs are planted in groups of four or five in a strong deep loam. Even in such positions it is an advantage after a few years to remove them to "pastures new," for, being of strong growth, they soon exhaust the soil. Perhaps no bulbous plants which adorn the garden in spring are so likely to be robbed of room as are these, and it is no unusual thing to see them fighting for existence with strong-growing perennials like Starworts or perennial Sunflowers planted in too close proximity. Planting the bulbs should take place quite early in September, and not, as it sometimes does, in late autumn. This is a point not always appreciated by those growing Crown Imperials for the first time.

A Charming Boragewort. Few will deny to the lovely *Mertensia primuloides* the highest rank among its kin, and the fact that it is not an easily satisfied plant in many gardens perhaps renders it even more attractive. *M. primuloides* makes a little tufty mass of rather hairy oval leaves some 3ms. high, above which are unfurled in the characteristic fashion of its race the lovely blossoms. To describe the colour of these is not easy. They open flat with a golden eye set in a strange mixture of the most delicate lilac and sapphire, which gradually passes into a most sumptuous and velvety rich violet. In a deep, free soil which does not suffer from lack of moisture in summer this pretty thing often does well, but it seems generally to succeed best with moraine treatment. Slugs are especially fond of it, but in spite of this and its uncertain temper it is an alpine that deserves any amount of patience and care.

FORTHCOMING EVENTS.

March 12.—United Benent Horticultural and Provident Society's Annual Meeting. Bath Gardeners' Society's Meeting.

March 13.—Royal Horticultural Society's Fortnightly Meeting (two days). Jersey Gardeners' Society's Meeting.

March 14.—East Anglian Horticultural Society's Meeting.

March 15.—Manchester and North of England Orchard Society's Meeting.

Answers to Correspondents

FLOWER GARDEN.

ROSES AND WATER LILIES (Felted).—Our correspondent should plant Rose Hugh Dickson. It is full, fragrant, free flowering and strong growing. The long shoots which this variety makes may be pegged down. It is a splendid bedding variety, flowering during a long period. The bottom of the lily pond may be covered with soil—good fibrous turves being suitable—but the plants generally succeed best when planted in baskets, the latter being placed on a few turves to keep them fixed till the roots become established. Many hundreds of Water Lilies are grown in ponds with unrestricted room.

PLANTS FOR A SHADY BORDER (H. C. G. N.13).—The following kinds of plants are suitable for the purpose: *Aquilegia japonica*, *A. j. alba*, *Anthriscum*, *Campanula*, *Columbine*, *Delphinium*, *Doronicum*, *Dicentra*, *Galega*, *Gaultheria*, *Hellebores*, *Hemerocallis*, *Hepatica*, many *Jakes*, *Mossy Saxifrages*, *Spiræa*, *Scillas* and *Violas*. Seeds of *Magnolia*, *Matthiola bicornis*, *Virginia Stock*, *Candytuft* and *Clarkia elegans*, all annuals, may be sown in patches near the front of the border to fill up and add to the display of blossom. In the autumn plant *Wallflowers*, double *Daisies* and *Polyanthuses* for spring display.

FRUIT UNDER GLASS.

HOW TO MAKE A NEW VINE BORDER (Hants).—When the ingredients to form the border are collected the border itself may be made. The whole of the base must be drained, using broken bricks or similar material to a depth of 9ins. The bottom should incline a little towards an outlet to ensure sound drainage. The border should be 2ft. 6ins. deep, not more, whole turves, grass side downwards, being placed on the rubble. The first portion of the border should be made 4ft. wide and 2ft. added each year till the allotted space is filled. Use the old fine rubble, but not any single nor sea sand. For every six barrowloads of the loam add 1 bushel of lime rubble, half a bushel of small bones, half a bushel of wood-ashes and 6lb. of bone-meal. The border, if made up before the summer, would settle down firmly and be in good condition for the planting of the Vines next November, the best time for an amateur to plant them. Cover the border during the winter with clean straw 9ins. thick.

MISCELLANEOUS.

BASIC SLAG (C. A.).—We have not heard of any ill-effects to chickens or animals from basic slag applied to grass-land. Basic slag to be effective this year should have been applied last autumn or early in the winter. It is very good for fruit trees and Strawberries, and should be applied to the soil about 6ins. below the surface when the ground is being prepared for the planting of fruit trees. 4oz. per square yard being a suitable quantity to apply. For the benefit of the Sweet Peas we advise the use of superphosphate of lime, now and when the plants are growing—2oz. per square yard now, and 2oz. per yard run of row later. The basic slag if in store should be retained quite dry till next autumn.

Illustrated Price Lists from the Makers:—

H. PATTISSON & Co., Sireatham, London.

The "PERFECTOR" ARCH forms an ideal setting for the Rose Garden. The man whose pride is in his Garden will appreciate the simplicity and effectiveness of this design. The construction is light, yet strong enough for a permanency, being specially designed for the cultivation of climbing Roses, Clematis, etc. It is made entirely of OAK and treated with Solignum, size 7 ft. high above ground level, and 3 ft. 4 in. wide inside. Price £1 each. Orders for three or more will be sent Carriage Paid. Cash with order. These can be made wider than 3 ft. 4 in. if required, prices for which will be quoted on application, stating number required.

THE

"PERFECTOR" PERGOLA.

This is constructed with the above Arches spaced any distance up to 6 ft. apart. The longitudinal and secondary cross bars to complete the Pergola are supplied in OAK, treated with Solignum, at 1/6 per foot run of Pergola; any lengths to suit your requirements. Thus the price of the Pergola illustrated, 25 ft. long, works out as follows:—

4 Arches at £1 each	£4 0 0
25 ft. run Top Bar at 1/6	£1 17 6

CARRIAGE PAID .. £5 17 6

State nearest Railway Station when ordering.

THE USE OF THE DAFFODIL

THERE must be many millions of Daffodil bulbs in Great Britain which are naturalised or—what is not quite the same thing—planted in turf. If we asserted that one-quarter of these were so planted as to provide something approximating to the maximum of beauty considering the materials and space at disposal, we should be unjustifiably optimistic.

In many gardens the practice seems to be to plant out each year in grassland the bulbs which have been forced for house decoration. These will almost certainly consist of a number of varieties—a comparatively few bulbs of each—belonging to almost as many different sections. As a rule no attempt is made to arrange the bulbs at planting-time, so that *Poeticus*, *Barrii*, *Incomparabilis* and the long trumpet varieties grow and ultimately flower in muddled clumps. Obviously, that is not the right procedure!

In works which deal with gardening from many aspects one not seldom sees it recommended to sow the bulbs from the hand over the turf-land and proceed to plant them where they fall. Now this is good advice as far as it goes; if carried out, it will prevent the equal spacing of the bulbs which is so irritating in planting which should look natural. It does not, however, go very far, since it gives no clue to the arrangement of the masses of bulbs, and this is the most important and, at the same time, the most difficult problem.

It has been said that an ounce of practice is worth a ton of theory. If we do not apply the proverb too literally, there is much truth in it. Certainly, as far as successful Daffodil planting goes, to see and to study a happy planting is a readier way of gaining information than reading pages of

instructions on the matter. This notwithstanding, the following suggestions may, perhaps, be helpful.

Drifts, that is irregular patches considerably longer in one direction than the other, look better than patches approximating to the circular. If there is one particular line of approach, these drifts should rather cross this line of direction than be parallel to it. Care should be taken to avoid a number of drifts of approximately equal size. It is equally important that the planting in the drifts should be irregular. If of equal density all over, it betrays at once its artificial character. Not only should the drifts be irregular in shape, but it is very necessary here and there to provide a few outliers a little distance away from the main body of the drift. If this is not done, Nature will probably in time remedy the matter by self-sown seedlings, but as the Daffodil seldom flowers under eight years from seed, this is rather a lengthy process!

Where patches of naturalised bulbs are already in existence which are from a pictorial point of view unsatisfactory, this is the season to peg

out improvements and also to mark clearly the stations of such groups as it is determined to lift and replant. This marking is often left until the foliage begins to wither, but it is safer to do it just as the blossoms are passing. Once the foliage begins to wither it very quickly disappears, and should something turn up to prevent the marking being done for a few days, it may be difficult or impossible to do it at all. It is surprising, too, what confusion arises as to the whereabouts of special varieties in grassland once they are out of flower.

A picture made up of not more than two varieties usually looks better than one composed of a greater number, but to the flower-lover with a limited area of ground at disposal this is a hard saying. To such, one can only point out the ideal and trust that they will restrict the number of varieties as much as possible. There is, of course, no possible objection to introducing bold breaks of the old Pheasant's Eye, *Narcissus Poeticus recurvus*, among colonies of early-flowering varieties, since the latter will long since

have been past when the Pheasant's Eyes expand.

In many gardens purple Crocuses—the deepest-coloured forms of *Crocus vernus*—are also associated with the *Narcissi*. *Crocus vernus* is later flowering than the so-called Dutch Crocuses, and makes a very pleasing contrast to the early Daffodils. Where a prolonged season of beauty is desired, however, it would be better to use the early-flowering *Cloth of Gold*. It is scarcely necessary to point out that the drifts of Crocuses, early and mid-season Daffodils and *Poet's Narcissi* need not be coterminous. It is quite feasible, even desirable, to form three separate garden pictures each totally dissimilar in outline. The dwarf-growing

A LITTLE COLONY OF THE DAINTY NARCISSUS TRIMON.

A SEA OF DAFFODILS AT WARLEY.

A SMALLER PICTURE. ALSO AT WARLEY.

STAR NARCISSI AND TRUMPET DAFFODILS INTERMINGLED.

Crocuses look admirable on the swell of a grassy bank, and generally it is well to emphasise with them convexities of surface. The Daffodils and, especially, the tall-growing Pheasant's Eyes look better and do better in the dips.

Tastes, we all know, differ, and it is difficult to select varieties for other people, but the following are all excellent for massing boldly in open grass-land. Narcissus Henry Irving is one of the earliest of the trumpets and very effective; another early and effective trumpet sort is Golden Spur. The old and rather dimmy-looking Princeps is yet splendid when seen in battalions in turf-land; indeed, it looks less stilted and more natural than many newer varieties with more substantial flowers. The writer does not care for the bicolor trumpets naturalised; they all look rather stiff and sophisticated. The creamy Mme. de Graaf, however, is exceedingly pleasing. No doubt the giant King Alfred will be largely used for naturalising when it becomes cheaper; its length of stem and undoubted grace is in its favour. For the present, however, the greatly inferior Emperor will have to deputise for his majesty!

All the Star Narcissi are beautiful when naturalised, but one of the most beautiful of the short-cupped sorts is Barm Conspicuous. This is plentiful and cheap, a good doer, and one of the most beautiful of Narcissi when naturalised. Another splendid sort is the old incomparabilis Sir Watkin; this is really one of the indispensable. On no account must the Feelsin section be left out. For naturalising, Duchess of Westminster or Mrs Langtry suggest themselves as suitable, but the delicate colouring and chaste form of this section is seen to best advantage when the grouping is a comparatively small one in a choice corner quite away from other sorts.

The late-flowering *Poeticus recurvus* will, of course, be included. *Poeticus poetarum* and the early-flowering but less substantial *Poeticus ornatus* will also be included by those who love the fragrant Poet's Narcissi beyond the others.

To naturalise Narcissi it is not necessary to have acres of ground at disposal; one of the most pleasing pictures ever seen by the writer was a simple grouping of the shade-loving white trumpet *moschatus* in a little plantation of Cob Nuts which had been allowed to grow practically wild. The Hazel in all its forms is very beautiful when bare of leaves in winter and early spring, most beautiful no doubt when laden with hoar or snow, but charming at all times. The ivory white of the Daffodils seemed more lovely than usual with the light chequerings of shade from the slender twigs of the Nuts.

Some of the tiny Narcissi that would dwindle away and die elsewhere will settle down and flourish in the rock garden. Such are the Hoop-Petticoat Daffodils, *Narcissus Bulbocodium*. The species has golden yellow flowers with a disproportionately large cup (petticoat), while the corolla segments are pointed and tiny. The White Hoop-Petticoat, *N. B. monophyllus*, is very lovely, but, like most African plants, needs special treatment. Outdoors a sun-baked place at the foot of a rock garden chert should be devoted to it. When growth starts, however, water should be given without stint. The Sulphur Hoop-Petticoat, *N. B. citrinus*, is a pale citron yellow form with larger blossoms than the typical *Bulbocodium*. There is also a large-flowered golden form, *N. B. conspicuus*. All the Hoop-Petticoats, except *monophyllus*, like a cool, moist, sandy soil rich in humus. They grow about 6 ins. to 8 ins. tall, and are very charming in the rock garden. The *Bulbocodiums* have been crossed successfully with *Narcissus triandrus albus*, and *Narcissus trimon*, portrayed on page 129, is the beautiful result of crossing *N. triandrus albus* with *N. Bulbocodium monophyllus*.

ORNAMENTAL FLOWERING WILLOWS

MOST Willows are grown by the gardener for their ornamental habit of growth, foliage or bark. There are, however, several among the two hundred or more species and hybrids with attractive flowers usually represented by the male catkins. This gives them an additional value for planting in wet and boggy ground or by the lakeside, positions where few flowering trees and shrubs are satisfactory.

In most Willows the male and female catkins are borne on distinct trees, those of the male being

leaves and catkins, 11 in. to 2 ins. long. It flowers, too, a month earlier. This year *S. Medemii* was in flower at the end of January, while *S. cinerea* is only now becoming attractive, the first week in March.

S. SMITHIANA.—This hybrid Willow is found wild in Britain, the suggested parents being *S. Caprea* and *S. viminalis*. The male form is a free-growing tree with large rich yellow catkins up to 1½ ins. or 2 ins. long.

S. CAPREA, the Goat Willow or "Palm," is perhaps the best known of all the Willows in country districts, the male catkins being associated with Palm Sunday. It is an attractive occupant of many a hedgerow, coppice and damp spot in woodland. It is, of course, common by the waterside.

S. CINEREA VAR. *PENDULA*, the Kilmarnock Willow, when grafted on a tall standard is a striking object in blossom in early spring with the pendulous branches clothed with male catkins.

S. CINEREA, the Grey Willow, is a large shrub or small tree, the male form gay in March and early April with yellow catkins, not quite so large as those of the Goat Willow, but sometimes used as a substitute on Palm Sunday. With us *S. cinerea* is taller in growth than *S. Caprea*, but with rather smaller leaves.

S. GRACILISTYLA, a native of Japan and Manchuria, forms a low spreading bush some 4 ft. to 6 ft. high. Very beautiful when in flower, it is one of the most distinct of the shrubby Willows.

S. BOCKII is a dwarf Chinese Willow first introduced by Mr. E. H. Wilson from Western Szechuen in 1908-9. For damp positions in the rock garden or for the

bog garden this species is one of the most distinct and valuable additions to dwarf shrubs of recent years. The narrow dark green leaves average ½ in. in length. The catkins of this Willow are produced during October and November before the leaves fall.

S. MAGNIFICA is another Chinese species. This remarkable Willow forms a very striking shrub or small tree up to some 20 ft. in height. It has red twigs and grey-green leaves with purple-tinted stalks, mid-ribs and veins. The largest leaves are up to 8 in. or 10 ins. long and half as wide, but 5 ins. or 6 ins. is a more usual length. The male catkins are 3 ins. to 6 ins. or 7 ins. long, the female ones 2 ins. to 3 ins. longer. Mr. Wilson describes this Willow as common at 7,000 ft. to 10,000 ft. in some parts of Western Szechuen.

A. O. Kew.

[The value of the Willow for decorative effect when in blossom seems to be but little appreciated.

Comparatively few people seem to be able to distinguish between the Sallow, *Salix Caprea*, and the other common native species, *S. cinerea*.—Ed.]

ROCK GARDEN CONSTRUCTION—III

IN the last article (February 24, page 94) we discussed the actual arrangement of the rocks to simulate stratification and to provide favourable conditions for the growth of rock plants. Let us now discuss the treatment of such rockwork in order to make it as effective as possible. Many amateurs have compared their own rock garden more or less favourably with the rock gardens in botanic gardens—those at Kew, Edinburgh, Glasnevin or Edgbaston, for instance, or with the one laid out for the Royal Horticultural Society at Wisley. If an amateur can show plants better grown than in these public gardens, he may legitimately congratulate himself on the fact, though at Kew and Edgbaston, for instance, bad atmospheric conditions have to be taken into account. Construction is, however, another matter. The necessity for providing easy means of access for large numbers of the general public is bound to detract in some degree from the appearance of the garden as a whole. This granted, it must be admitted that the general lay-out of public gardens has become stereotyped, and it is unfortunate that greater efforts are not made to reproduce in our public parks and gardens the features which make a well laid out private garden so satisfying and so restful. In no way could the public taste be more readily improved.

Of the gardens mentioned the most unsatisfactory from a pictorial standpoint is Glasnevin; Kew is little better; Edinburgh and Edgbaston show a distinct improvement; but, unquestionably, the Wisley garden is better designed than any of the others. The greater the pity that it is so very inadequately maintained!

As a general rule the difference in height between the valleys and the hills in our rock gardens is insufficient to produce the effect we have in mind. We therefore proceed to accentuate the difference by planting. For the valleys we use plants of a low and spreading habit of growth; on the hills we employ those of upright habit, or shrubs and trees of comparatively large size. If the lowest feature of our garden is a pool, we shall, naturally, wish to use some of the sword-foliaged semi-aquatics so characteristic of pond-side vegetation. We should, however, employ these rather sparingly, lest a mass of tall Rushes or what-not compete with, and so render ineffective, our cliffs.

It may be argued that the method of planting shrubs—mostly conifers—above our high alpine is unnatural, since, of course, many of these plants in their native rocks grow far above the timber line, some of them, indeed, close up to the permanent snow caps of the mountains. Plants grow in rocks, however, at low elevations as well as at high ones, and we can scarcely hope to portray an alpine mountain-side in our garden; even if we could it would sort ill with other garden features. Readers who visit Chelsea Show will have noticed that even the craftsmen who depict Yorkshire moors so effectively always imagine the highest points to be capped with forests of Fir or Larch!

The type of shrub employed for background will depend very largely upon the size of the garden in question. In large gardens any conifer which has—shall we say?—a crooked disposition (and a few such are to be found in almost every batch of seedlings raised) may be employed

HANDSOME CATKINS OF *SALIX MEDEMI*.

by far the more ornamental. With the majority the catkins appear in early spring in advance of the leaves on the shoots of the previous summer's growth. The most notable exception, as far as these notes are concerned, is *Salix Bockii*, which produces its catkins in the autumn. Male and female are borne on separate plants, but in this species both are pleasingly attractive. The following are worthy of special attention as flowering trees:

S. MEDEMI is not only one of the most attractive Willows in flower, but also particularly interesting, because male and female flowers are borne on the same catkin. In most Willows the male and female catkins are borne on different trees. *S. Medemii* was at one time classed as a variety of the Grey Willow, *Salix cinerea*, but most authorities now accord it specific rank. As a tree for the pleasure ground or waterside it is readily distinguished by its more vigorous habit and larger

effectively. Its crookedness may be maintained and accentuated and its size be held in check by the judicious use of the pruning knife. Atlas Cedars often shew this tendency to deformity, while the glaucous and golden forms of this Cedar are often, in foreign nurseries, grafted on Larch. So worked, they seldom or never make specimens, but they are excellent for the rock garden. Again, grafted Spruce and Fir, if they are to grow into

filifera nana and lycopodioides; and various others.

It is easy to arrange a rock garden to accommodate any plant or race of plants which we may fancy; easy even to rearrange the garden for them when the construction has been completed a number of years. As regards the shrubs which are to give height to the cliffs, the case is, however, different. The specimens need choosing very

FIGURE 9.

straight, clean specimens, must have the grafts cut from leaders (or prospective leaders), but those grafted from sprays of the branches and which have, in consequence, a tendency to sprawl are admirable for rockwork.

The shrubs so employed should always seem to lean outwards from the cliff, as though a series of violent gales had partly loosened their root-hold on the edge of the precipice. A few conifers which may often be found deformed in nurseries may be useful. Such are *Cedrus atlantica* (all forms), *Picea excelsa* (Spruce), *P. pungens* (particularly the variety *glauca* Kosteri), *P. Pinsapo* (Corkscrew Fir) and variety *glauca*, *Juniperus communis* and *J. virginiana*. Besides these there are a number of recognised dwarf species and varieties which are admirable for rockwork. Such are the Mountain Pine, *P. montana* (syn. *P. Mughus*); the Swiss Pine, *P. Cembra*, slow growing, but attains some size at last; *Cupressus obtusa densa*, very quaint and beautiful; various dwarf forms of the Spruce, *Picea excelsa*—*pygmaea*, *Remonti*, *Clanbrassilliana*, *Maxwelli*, *procumbens*, etc.—and of the *Orientalis* Spruce, *P. orientalis*—*pygmaea*, etc.; at least two Firs, *Abies canadensis* *Sargentii pendula* and *A. balsamea hudsonica*; a great number of Junipers, including five or more dwarf forms of the Chinese Juniper and as many of the Savin, *Juniperus Sabina*, which is, in its typical form, suitable for the large rock garden—*Juniperus S. prostrata* and *J. S. tamariscifolia* are especially useful; several forms of *Cupressus Lawsoniana* (generally listed as *Retinosporas*), such as *tetragona aurea*, *pisifera nana*,

carefully in the first instance; they will first be selected to fill the special sites which call for them and then the arrangement of the rockwork will be so modified as to shew them to best advantage. The trees on the cliff are as essential a part of the rock garden as the stones of the cliff itself, and no pains should be spared to get suitable specimens in the first place or, afterwards, to provide for them the precise setting they require.

Years ago rock gardens were often monotonous

FIGURE 10.

successions of pockets, as in Fig. 9. These pockets were usually cemented up, presumably to prevent runners of any plant employed finding their way to the space (pocket) devoted to another species or variety. Quite a number of rock gardens on this ridiculous system have been built in this,

the twentieth century! This construction is called to mind not from any fear that readers will perpetuate it, but because, when working with stones laid in courses to simulate natural strata, the "pocket" effect becomes, on sloping banks, almost inevitable, and considerable care is needed to prevent the monotonous effect occasioned by pockets of approximately equal size. Fig. 10 suggests how the difficulty may be overcome, but it must be confessed that just as some people when planting for natural effect seem unable to avoid arranging the plants in a monotonous quincunx formation, so, when building a rock bank other folk (or more probably the same ones) seem unable to avoid a deadening uniformity. For the sake of clearness the diagram is merely a plan and the minor projections and "inlets" so natural and beautiful in rockwork have been omitted. The tiers are numbered 1 to 5, 1 being the lowest. Where tier 1 disappears under tier 2 or tier 2 under tier 3 will be practically a perpendicular cliff. Where the tiers run very close together (as on the left-hand side of the valley in the diagram) the rockwork will also be practically precipitous. Valleys such as the one shewn produce a much-needed diversity, and should be used as freely as the site permits. Sometimes it is possible to arrange two which debouch close together, leaving an isolated bit of cliff between them. Even when no valley is planned, it is well occasionally to leave an outlying piece which looks as if it had become detached from the cliff behind. Such a one is shewn marked 2x in the diagram.

FIGURE 11.

If at the foot of a cliff of some height and themselves of comparatively small size, such stones need not be lying in conformity with the surrounding "strata," for they may be supposed to have fallen from the cliff above.

Now a few words must be written about the arrangement of the individual stones. Almost every stone has its best face and its better bed.

After what has been said it may be superfluous to mention that every stone should be laid according to its natural bed—that is to say, that no shortage of material or desire for economy must tempt us to set stone with the "grain" up hill, as in Fig. 11c. Not only does such an arrangement not appear natural, but the stones thus up-ended are almost certain to split in frost, converting the rock garden into a rubbish-heap.

Quite a number of pieces of rough sandstone for rockwork ("rockery burrs" the quarry owners call them) will be found to bear some resemblance to the piece depicted at A and B in Fig. 11.

As seen at A the bottom is somewhat rounded and the top is level except towards the front. The amateur rock garden builder usually turns the nice level face downwards, thinking to make it solid, and leaves the ugly convex surface upwards as shewn at B. This is, of course, quite wrong; if the top of the stone is to be exposed to view always select one on the hollow side. Any

uncomfortably square corners or edges can be knocked off with a fairly heavy hammer—a quarryman's hammer for choice. Even in removing edges take care not to produce too even an effect. Do not spare an ugly edge just because it is lichened. If the ugly angles are knocked off the lichen will soon reappear.

(To be continued.)

SOME MARSH-LOVING PRIMULAS—II

The Candelabra Section

TO this section belong some of the stateliest members of the whole genus, many of them being of great horticultural value. Their flowers are borne in several successive whorls one above the other on stout stems from 1ft. to 3ft. high. They revel in moist conditions where water is within reach of their roots, but at the same time most of them can be grown in drier situations. A good, deeply worked, loamy soil is essential under the latter conditions, combined with partial shade. They are readily raised from seeds when the latter are fresh. The seedlings should be pricked off into shallow boxes when large enough to handle and grown on in a cold frame till they are fit to plant out. The best time for planting out these Primulas is the early autumn. They then get established before the winter and are ready for pushing up their flowers in due time.

P. BEESIANA.—This is a new and handsome species from North-Western Yunnan, where it was found by Forrest and named in honour of the firm of Bees, Limited. It is a lover of moisture, and Forrest says that it forms huge colonies in its native habitats, often covering many acres. The situations favoured are moist, gravelly meadows along the margins of small mountain streams, where pure spring water percolates through the light soil. Excepting in colour *P. Beesiana* is similar in habit to *P. Bulleyana*, much the same in height and quite as robust. It possesses equally luxuriant foliage, but differs in having a dull red midrib to the leaf. The flowers are borne in from five to seven whorls, with twelve or more in a whorl, and are of a rosy carmine colour with a bright orange eye. Well grown plants attain to a height of 2ft. to 3ft., while the flower-stems are numerous and towards the apex densely coated with a white farina. Although not a perennial species, it is quite hardy, and reproduces itself freely from self-sown seeds.

P. BULLEYANA.—Another of Mr. G. Forrest's finds in Yunnan, where he says it grows in "moist open situations on mountain meadows on the eastern flank of the Lichiang range at an altitude of 10,000ft. to 11,000ft." It was named in honour of Mr. A. K. Bulley, who has done so much in the way of introducing new plants into cultivation. A first-class certificate was awarded to it at the Temple Show of the Royal Horticultural Society in 1909. Like the above species, this plant has a series of whorled flowers in tiers on scapes about 2½ft. high. These are of a buff orange shade when fully open, but in the bud stage almost rival in intensity the colour of *Cockburniana*. The plant is perennial, quite hardy and produces seeds freely. It crosses freely with *P. Beesiana*, and there are numerous hybrids of various shades of colour in cultivation.

P. COCKBURNIANA.—This is one of the plants introduced by Messrs. Veitch from Western China, where it was found by Mr. E. H. Wilson growing in wet alpine meadows at an elevation of over 10,000ft. The bright orange scarlet of the flowers

is unique in the genus, and has been taken advantage of by the hybridist. The small primrose like leaves are produced in a rosette, from which the erect flower-scapes rise to a height of 1ft. or more. These bear three or more whorls of flowers, each about 1in. in diameter. Unfortunately, it is only a biennial, but it produces seeds freely, and they germinate quickly if sown when fresh. This species has been crossed with *P. pulverulenta*, and as the latter plant is more of a perennial, the hybrid, which is called *P. Unique*, is a stronger-growing plant than *P. Cockburniana*. Its flowers are mahogany red, lit with orange.

P. HELODOXA.—This handsome yellow-flowered species is one of Forrest's finds in Western China.

seeds freely and reproduces itself. Growing over 2ft. high, the stems bear several whorls of various shades of colour from deep crimson to pure white. Seeds come up freely when sown as soon as ripe, but if allowed to get dry they take a long time to germinate.

P. LUTIFOLIA.—A handsome plant from the Eastern Caucasus, with bright green leaves and whorled umbels of yellow flowers. Somewhat rare in gardens, it is well worth growing in moist situations.

P. POISSONI.—Comes from the mountains of Yunnan in Southern China, and is quite hardy in ordinary winters when planted in a rather sheltered place. In habit it is something like *P. japonica*, but is easily distinguished by its glaucous leaves. Growing about 1ft. high, the violet-rose coloured flowers are disposed in whorls of eight or more on each. It usually dies after flowering. Closely allied to this is *P. Wilsoni*, also from Western China, of similar habit, but rather more hardy in this country.

P. PULVERULENTA.—This fine plant, which was introduced into cultivation by Messrs. Veitch, and found by Wilson in Western China, was at first considered to be a form of *P. japonica*. It has, however, distinctive characters and deserves to rank as a species. In habit it somewhat resembles the above plant, but differs in having larger, more richly coloured and more elegant flowers, and in the flower-stems and calyces being thickly

PRIMULA UNIQUE (*P. PULVERULENTA* *P. COCKBURNIANA*).

It was first shewn in flower by Messrs. R. Wallace and Co. at the Chelsea Show in May, 1916, and created a very favourable impression. The whorled stems reach a height of over 3ft., and carry seven or eight tiers of soft yellow flowers that bear a striking resemblance in size and colour to those of *Jasminum primulinum*. It has proved to be a good hardy perennial, flowering for several seasons, but, like many other Primulas, it is in some places a short-lived plant. Under good cultivation and in moist situations it attains to a great size, with luxuriant foliage and very stout stems.

P. JAPONICA.—This well known plant is an old inhabitant of our gardens and so well known that it needs no description. It is highly valued for planting in groups by the waterside, where it

coated with a white mealy powder. In strong, moist, loamy soil the stems rise to a height of over 2ft., and bear tiers or whorls of crimson-purple flowers. There is a beautiful variety of this species with whitish pink flowers named Mrs. R. V. Berkeley, and one of deeper salmon-rose colouring of uncertain nomenclature. Many consider *P. pulverulenta* the best of this section.

P. SMITHIANA.—This elegant plant is the Himalayan counterpart of the Chinese *P. helodoxa*. There is some doubt as to whether there is any real difference between the two. Growing in similar situations last summer, they appeared to be identical. Our *P. Smithiana* was raised from seeds received from Calcutta, and no doubt represented the Himalayan species. W. J.

GARDENING AT OLYMPIA

THE "Queens' Gardens" at the Home Exhibition are, on the whole, more spectacular than practical. It is useless to pretend that they are as helpful to those in search of gardening ideas as the model gardens at Chelsea, for instance, yet when the unnecessary striving for effect has been discounted, there are many helpful gardening features at Olympia.

I am by no means certain that Messrs. Child's little garden around Messrs. Oetzmann's bungalow in the new annex is not the most helpful gardening contribution to the Show. Probably the attempt has been made to do a little too much in the space at disposal, which is very small, but, at any rate, one can see here a simple practical method of treating the surround of a small house which might cause envy or provoke imitation, but which would certainly not provoke laughter or pity!

Returning to the "Queens' Gardens" the oftener we return the better for the hospitals, let us examine Mr. Whitelegg's little rock garden. To appreciate this as it should be appreciated we have to take a pillar "out of our eye" and to give it the needful setting of green turf and a fitting background of trees and shrubs. It is then a very pleasing erection for a small garden.

Messrs. Gaze's formal garden, a corner of which is illustrated herewith, grows on one with continued acquaintance. It has the great merit of restfulness, which so many of the exhibits here lack. Even the horrible blue lighting, which has the extraordinary property of making the various tones of mollis Azaleas, in the adjacent Queen of Spain's garden, clash, cannot disturb the quiet of this garden. Mr. Whitelegg is responsible for the garden of the Queen of Spain, and one feels that under natural lighting it would have its points, especially in the sunny Southern Counties. The planting is a little on the thin side, and the line of columns which give weight at one end of the garden would certainly be better joined at the tops by timber.

Messrs. Carters have depicted an informal spring garden and, considering the difficulties of the site, have been successful, albeit I much preferred their more formal construction of last year. The present effort is a little over-planted, and the central section is less interesting than the two wings. The finish also is not quite so good as one generally gets from the Raynes Park firm. A little stream meanders along the centre, with here and there a stony outcrop and ledge of rock, and, in the turf, Narcissi, Tulips and other spring flowers are planted. There would be little to see at any other season.

Messrs. Hodsons have a formal garden, which is quiet enough and well finished, but the watering is too heavy for the size of the plot enclosed, and which therefore seems over-scalded throughout.

Below Windsor, near the station at Egham, is a model garden which shows a simple and effective way of setting out a small garden. Models such as this are of little use to many people who cannot reach a garden, or see a garden from a plan. On the other hand, they do very effectively the treatment of a considerable area which it would be quite impossible to exhibit life-size.

The other exhibits are interesting on a general level, some of them, however, but have little practical value. R. A. G. W.

MR. G. G. WHITELEGG'S LITTLE ROCK GARDEN.

ONE END OF MESSRS. GAZE'S EXHIBIT

A GLIMPSE IN MESSRS. JAMES CARTER'S GARDEN.

THE WOODLAND GARDEN IN SPRING

SOME of the most precious of spring's early greetings come from the Dog's Tooth Violets (*Erythronium*), which seldom seem so happily placed as when they appear among the leaf-drift and wintry herbage of some sunny woodland slope. They bridge the time between the Snowdrops and wild Hyacinths, and are possessed of that tender elegance and grace which one instinctively associates with the spirit of youthful spring. The spontaneity with which they arrive is also in harmony with that impression. The old *E. Dens-canis*, in particular, with its mottled leaves and flowers in various shades of rose and purple, seems to leap out of the ground within a few hours, only to wait with closed flowers should the skies be grey for the sun to open and reflex their pretty rays.

The smaller *E. americanum*, in pale yellow with brown markings, is a shy little plant that can be comforted with a cool, not too shady place, and another good one, if not the best, is *E. revolutum* Watsoni, which usually closely follows the above. The large, ivory white blossoms of this variety, with their ring of gold and beautifully reflexed segments, suggest, in suitable surroundings, the very acme of good taste.

But one must pass over the rest of this charming tribe and come to the little Daffodils of the Welsh hills which, even though they may be deafened by the trumpeting of the bigger and bolder productions of the hybridist, still bear a charm of their own which none can usurp. This diminutive native, if it may be so termed, on a 4in. to 5in. stem, though it spreads freely and swarms in large colonies in all manner of situations, never seems to vary in the minutest degree. The blossoms are all as much alike as the proverbial peas in a pod, the perianth, which lies almost flat on the trumpet, being a shade less golden than the latter.

Another bulbous plant that has had good reason to rejoice in the shortness of its stem during the recent weeks of windy weather is *Leucojum carpaticum*. This is in every way superior to *L. vernum*, of which it is said to be a form, the white bells being rounder and ampler and adorned at the tip of each segment with a blotch of gold. This is as easy as *L. vernum*, which is to say that once it becomes established it will prove not only permanent but progressive. One's stock will shew an increase with each recurring spring. *L. carpaticum* is, of course, a plant for the edges of walks and short herbage or grass. Where *Scilla sibirica*, *Anemone trifoliata*, Grape Hyacinths, Primroses and Cyclamens are colouring the woodland floor without having to contend with things of ranker growth, *L. carpaticum* will be quite happy.

L. æstivum, on the other hand, is grateful for the support of even such tall-growing things as *Erica darleyensis*. Though called the Summer Snowflake, this species is often in bloom here in April, and this year it will be even earlier if one may judge by its tall grass green leaves which are already standing out of the Heaths, among which it has grown for many years.

The Snowdrops, which so thoroughly enjoy life in this woodland garden, also appreciate some support, though it must be admitted that, being practically wild, their carpeting is a matter of accident rather than design. Among the lingering fragments of winter none looks quite so effective as those Snowdrops which have colonised a bank covered with Ivy about 8ins. thick. Here the bells are not only finer, but, owing to the fact that the plants have to grow stems at least 1ft. long before they are sufficiently clear of the Ivy to flower, they are invariably later by some three weeks than those which have no such covering.

The *Megaseas* afford a touch of colour at this season which is uncommon in the woodland garden, yet one that is in no sense out of harmony with the environment. Their fine leafage is alone sufficient to merit them a place. Indeed, if it were not for this it is probable that some of us would never grow them at all, since they are not the most reliable of bloomers. Here they bloom, but if this effort is somewhat niggardly, it is enough—with their foliage—for our purpose. Lime and more exposure, plus a more rocky root-hold, is probably what they really crave for. The finest plants in regard to number and size of flower-heads of *M. cordifolia* I have ever seen were growing in the old mortar on the top of a tall brick wall!

Though one would not like to be without them, the *Pulmonarias* are not an exciting race. Yet they seem to be the "right thing in the right place" when set in some sunless woodland corner, which they will do their best to enliven with the blues and purples which are so dimmed by those of some of their brilliant cousins among the *Anchusas*, *Omphalodes* and *Borages*. The true native Dorset form of *P. saccharata*, said to be the best of the tribe, is still on the "wanted" list in so far as we are concerned, but we make shift with *P. arvernensis*, quite good in the blue and better still in the white form. Then there is the plain green and narrow-leaved *P. angustifolia azurea*, a really fine blue, and Mrs. Moon, biggest and earliest and most spotted of all. If the *Pulmonarias* as a race do not arouse one's enthusiasm, they are brave and ask little, go their own way and never interfere.

Though yellow is a predominant colour at this season, there is no shrub or plant now in blossom which can equal in richness of tone that of *Coronilla glauca*, of which the rounded beads of fragrant blossom are rendered even the more attractive by reason of their backing of pretty, pea-green foliage. The yellow of *Cytisus purgans*, perhaps, comes nearest to that of the above, and this is such an early and prolific little Broom that it deserves to be more widely grown. It often precedes *C. præcox*, which has purgans blood in it, by three weeks or a month, and if the habit is somewhat stiff one easily overlooks this when the 3ft. shrub is a dome of pure gold.

Cytisus racemosus (fragrans), which has been flecked with blossom all winter, now breaks into fuller colour with *Genista monspessulana*, which also has been waiting in a dog's sleep for the first reliable hint of spring. The latter is a perfectly hardy and first-rate shrub for massing. Like *C. racemosus*, it is very leafy, is seldom out of

flower, and becomes a mass of yellow in April. It will go up to 6ft. or more, but young plants are best and they grow from seed like grass.

Among the Barberries the most forward in blossom at the moment is *Berberis pruinosa*, of which the arching wands are hung beneath each rosette of pale green leaves with a cluster of creamy yellow blossoms. These are followed by white berries, which will remain on the bush until the new flower-buds are thrust out. *B. Darwinii*, so early this year, is almost as magnificent in the fiery vermilion and tangerine of its half-open state as when laden with full-blown blossoms, and another which is marking time with the above is the always tidy and well dressed little

ADMIRABLE FOR WOODLAND, *ERYTHRONIUM REVOLUTUM*.

B. dulcis nana. Not so forward, yet so generous with promise that one cannot pass it by, is *B. Sargentiana*. Very striking in the clear March sunshine are the plum red bud clusters, the ruddy bark, handsome leaves and awesome spines of this fine species.

Not less attractive in quite a different way are the wine-coloured stems of *Rosa rubrifolia* and the peculiar tone of bluish red which pervades the young foliage. Though one does not usually expect much in the way of reds at this season, it is odd to see the Hollies still carrying their full Christmas complement of berry. *Cotoneaster pannosa* is also as lovely as it was at the turn of the year, its elegant and evergreen branches being borne down even now with the weight of their crimson-scarlet burden. The *Pernettyas* also are still carrying their old fruits, and will continue to do so for many weeks, despite the fact that their fine, glossy green foliage is already

peppered with a multitude of flower-buds and many fully expanded blossoms.

Erica carnea has almost reached the fulness of its splendour and won fresh laurels for so bravely withstanding the gales and hail and deluges of rain which beat upon it during February's last week. Having done all this and more, the splendour of the Heath bank will pass to *E. mediterranea*, whose tall, erect branches are already well on the way to full flower. This fine Heath is to early spring what *E. carnea* is to winter, a beautiful and robust species of the utmost value for massing or planting singly. Contemporary with it in

blooming is its variety *E. m. hiibernica*, and before these are going off the exquisite white form (*alba*) will open its lovely blossoms. These are already swelling in the bud, as are those of that other noble variety, *E. m. var. superba*, which is bigger and even better in all its parts than the type— which is saying much. This admirable Heath is usually listed as *E. m. hybrida superba*, but I think this must be an error, since it is more akin to the type species in form and colouring. Its foliage is slightly more glaucous than that of the latter, but it flowers at about the same time, that is, from March to May. NORTH WALES.

NOTES FROM THE EDINBURGH ROYAL BOTANIC GARDENS

IF one lives near a great botanic garden, such as the one at Edinburgh, it can be made the source of real practical help to the everyday garden lover. We shall find there innumerable plants from all parts of the world, tested and grown under various conditions, in different soils and situations, till that which suits best the particular needs of each individual is found. Many of us do not realise what a help it would be if we went to study these methods; or, again, to look at many plants that we have hitherto only heard or read of in catalogues, and it would enable us to decide whether they were suitable for our own gardens. Some plants may still be too scarce for general cultivation, others may prove unsuitable for various reasons. But at any time of year a visit will provide a fund of information and a guide as to what plants we may grow and how best to grow them.

Take the month of February, for instance. There are, among Rhododendrons alone, some kinds that will fascinate the most ardent botanist, and others that can be of great use for ordinary garden effect. In the rock garden at Edinburgh there is that remarkable little species, *R. nivale*, found by Hooker in the 'fifties among the Himalaya mountains at a height of 17,000ft. or more. As is to be expected from such an altitude, it is a tiny, low-growing species, its little creeping stems set with minute rounded leaves and small mauve-pink flowers, which opened this year about the middle of the month. This little rarity is not, of course, for everyone to grow. It is there for us to enjoy and wonder at, to remind us of the marvellous diversity of these shrubs, from this humble example to those that grow into noble forest trees, 40ft. or more in height, and again some with foliage a mere rounded dot in size to those bearing broad and leathery leaves like *R. Falconeri* or *R. sino-grande*. There is also out during February a species that is still somewhat rare, but can be now bought from nurserymen. This is *R. moupinense*, which has proved itself to be of easy culture and is so showy and free-blooming and fragrant that everyone should try to grow it. It may be seen at Edinburgh growing both in the rock garden and in a long border set apart for Rhododendrons, while Miss Willmott speaks of it as a very beautiful pot plant, so its uses are evidently manifold. It forms a neat, sturdy little bush some 18ins. high, of which the evergreen leaves are almost completely hidden by masses of comparatively large white flowers, which are of good substance. These may suffer during very severe weather as they open with the first days of the month, but a succession of buds opens continuously till the middle of March, when the little plant settles down to take a well earned rest. I have watched this little Rhododendron now since 1914 and it is by making such visits and notes that

the amateur gardener can learn what are really good plants for his own use. Another Rhododendron that we might well use more widely is *R. præcox*, which is well shown at Edinburgh, both in a large bed and as a long, low hedge some 3ft. or more high. It is a hybrid between *RR. ciliatum* and *danicum*, and for general purposes seems better than either, as it has more showy and larger flowers than the latter and is harder than the former. It is, indeed, a lovely and profuse-blooming kind, of a soft rose-pink, and as it is now cheap, it should be planted in groups or as a low hedge, setting the bushes 2ft. to 2½ft. apart.

Two species called *R. parvifolium* (2½ft.) and *R. capponum* (10ins.) are out in the rock garden, but these are small-flowered and of a somewhat ugly pink colour, combined with straggly habit of growth. Among Primulas, that pernickety species *Winteri* may be seen in full bloom under an overhanging ledge to keep the plants dry and to prevent "damping-off," which is what so often happens to them. *Ribes laurifolium* is grown both as a rock plant and in a bed by itself in another part of the Garden, and in both places it appears a desirable little shrub for its large evergreen leaves and pretty, though inconspicuous, racemes of palest greenish-yellow flowers which unfold at this time of year. A most beautiful little Vetch

called *Lathyrus vernalis* var. *azureus* is beginning to flower in the rock garden, and is an invaluable plant for any purpose, and its blue-shot-lilac colour is both unique and pleasing. It forms a small clump about 15ins. high and can be grown in ordinary beds, while it may be seen most happily naturalised under Pine trees in another part of these Botanic Gardens—a hint that is worth remembering for those who like wild gardening.

A visit to the alpine house at Edinburgh will always have a particular interest from the fact that there the plants are not in pots or pans, but are growing permanently in the fine rockery of red sandstone that has been erected under glass. There are many flowers out now, and one of the most interesting, perhaps, is *Gentiana rhodanthe*, from China, which I saw there first on January 8, 1921, a small, upright plant some 15ins. high, bearing numerous pale pink flowers, tubular in shape, opening widely at the mouth. Here, still, in February, 1923, it is growing well and blooming as freely as ever.

Corydalis thalictrifolia is also an old inhabitant and is producing as freely as ever its long, yellow, tubular flowers. The foliage is pretty and it grows about a foot high. These two plants may be taken as typical sorts for such a cold glasshouse, which, by a suitable choice of herbs, bulbs and small shrubs, may be kept full of bud or bloom or berry all the year round. M. E. STEBBING.

LENTEN ROSES

THE hybrid Hellebores which are commonly in gardens called by the above name are subdued in colouring, but none the less beautiful for that. They like a woodland soil, and are seen to best advantage beneath the shade of trees or bushes and in company with Ferns. The fine hybrids which may now be procured in many shades between pure white and deep purple appear to be of German origin. Some of the best varieties were raised by a well known nursery firm of Erfurt. They are, however, readily obtainable in English nurseries, and should be more extensively planted. For the first season they should be guarded against drought. It is a good plan to mulch the crowns with any light spent manure or, failing this, with Wakeley's Hop Manure.

LENTEN ROSES AT MUNSTEAD WOOD

CORRESPONDENCE

WISLEY GARDENS.

A VISIT to the Royal Horticultural Society's Wisley Gardens in the early part of the summer of 1922 for the special purpose of seeing the rock garden at what should have been a most interesting period proved to be most disappointing. Weeds were too much in evidence, and it was very much overgrown and the plant-labels were, for the most part, either missing or overgrown. The fault does not lie with the gardener in charge, whom I believe to be a most capable man, but is due to this part of the gardens being obviously very much understaffed. There should be a permanent staff sufficiently large (apart from students) to keep the part of the gardens set apart for plants and shrubs of botanical interest in reasonably good condition and to develop it on proper lines so that it may be a resort where one can see what is possible in outside conditions in that part of the country. While it is necessary that the outlines of the garden should be developed on as natural lines as possible, it is possibly more important that the many now interested in rock gardens should be able to see individual plants or groups of plants and the conditions in which they are found to thrive best. Experiments should be made as to soils and aspects for the many plants that, for want of proper understanding, may, although very desirable, be found difficult by many. Take, for example, the Saxifrages, including the innumerable hybrids (Kabschias and others), that have been introduced in recent years; it should be possible to see the growing outside without protection (except for early-flowering species when coming into flower to protect the flowers and lengthen the period), and these should be plainly and correctly named. There are also the various dwarf Gentians, Acantholimonas, Ethionemas and Androsaces, recent introductions from Tibet, etc., and endless others, including the various Crocus and Tulip species and other bulbous plants. An indication should also be given on the labels as to the date when planted, so that information could be obtained as to the permanence of the plant. It is not nearly so interesting to see plants that have been brought on in frames in more or less artificial conditions. What the members (and there must be a large number interested) want to see is the possibilities under natural conditions. This applies not only to alpine but to herbaceous plants and the numberless shrubs, etc., that are, or may be, introduced into this country not only from the intensely interesting expeditions into the wilds of China, Tibet, Burma, etc., but from all parts of the world. Why should it not be possible to have a part of the gardens comparable to the "Mecca" of alpine plant-lovers, the Royal Botanic Gardens at Edinburgh, which in the autumn of 1921, after the very dry summer, was so interesting as to make one loath to leave it.—T. A. L.

PRIMULINUS HYBRID GLADIOLI.

I READ with much interest "Amateur's" article on "The Invaluable Gladiolus" in the issue for March 3, and thinking it would be of interest to many lovers of this unique flower, I take up his suggestion of naming another dozen primulinus hybrids which are exceptionally beautiful. First, however, may I point out that the variety so excellently illustrated is named *Unsurpassable*, and however much we may condemn the prefix, it is Mr. Grulleman's doing, and we must accept it, and not raise confusion by calling it *Unsurpassable*. No dozen would be representative without Alice Tiplady, Woodcote, Orange Brilliant or Maiden's Blush, so I must

borrow these from "Amateur's" twelve and add the following: Altair, a delightful blend of soft salmon saffron, very "smooth" in colour tone and making an extremely beautiful table

PHEASANT'S EYE NARCISSUS GROWING WILD AT LES AVANTS, SWITZERLAND.

decoration. Anamiosa, a large-flowered "Prim." of spreading petal, soft salmon with large golden throat. Buttercup, pretty butter yellow with red lines on lower segments, neat grower. Capella, bright fiery orange red, a tall and handsome plant. Eden.—This variety was repeatedly pointed out by visitors last summer as one of the most beautiful. The upper petals are flesh blushed with pink at the edges, lower segments ivory white edged with pearly pink, canary yellow throat; a tall grower. Fire Queen, brilliant scarlet with greenish yellow throat. Otranto, a very lovely maize yellow with rich red throat markings and beautifully flushed on the outside of the shoulder petals. Sunrise, a prettily crimped or ruffled flower, bright yellow with pink suffusion. All too soon the dozen is completed and another two dozen or more just as beautiful not even mentioned. Will someone else step in with a further consignment?—J. L. G., *Crawley Down*.

ROSE MARECHAL NIEL.

THE most beautiful Maréchal Niel Rose that I know covers the front of this villa. I see that it is grafted high up, about roft, from the ground, on the stem of a Banksia Rose. It must be of great age, for the stem is as thick as my arm, and it is in full vigour. Is the parentage of Maréchal Niel known? Is there any Banksia blood in it?—L. Jounston, *Villa Mer et Monts, Menton A. M., France*

[Except that it is classified as a Noisette, we are not aware of the parentage of Maréchal Niel, but unquestionably it is longer lived under glass on the Banksian stock than on the Briar. Perhaps some reader knows the parentage of this grand old Rose?—Ed.]

THE PHEASANT'S EYE NARCISSUS.

PERHAPS the enclosed picture of Poet's Narcissi growing wild in Switzerland may be of interest. The more boldly they are massed the more effective they are. English gardeners please note!—S. S.

[In this country the Pheasant's Eye Narcissi likes rather damp soil and has no objection to the partial shade afforded by orchard-trees.—Ed.]

ABOUT FREESIAS.

"DUDS" have been more numerous with me this year than I ever remember before. Some of my bulbs are only just now starting, although standing alongside pots which are rapidly passing out of bloom. I am inclined to agree with the Rev. Joseph Jacob that the open flowers are more taking to the eye than the cup-shaped flowers, but at the same time some of the latter varieties are more deeply coloured. May I say that while being disappointed with my Freesias this year, I have been delighted with the flowering of another of the Rev. Joseph Jacob's pets—the *Lachenalia*—Ostend, Riga, Greenland and Boston, to mention just a few, being particularly fine and striking.—G. C.

I WAS very pleased to see Mr. Jacob's notes in *THE GARDEN* of March 3. His Freesias seem very much more forward than mine. Perhaps he gives his more heat than I do. I have as yet very few out. I have never been troubled with "duds" in my own stock. My theory all along has been that this fault is due to insufficient ripening of the corms. Even after the cold, sunless season of 1922 I have less than one per thousand. A thorough roasting in their pots after the foliage has died down and to keep them warm and dry afterwards has been my treatment. If Mr. Jacob will try this, I feel sure he will not complain of "duds." Like Mr. Jacob, I have for the first time found a plant with variegated foliage, the only one out of some five thousand

seedlings. As it has not yet flowered, I cannot say whether it is worth keeping. The album form that Mr. Jacob refers to appears also, but I put it down as a weak, anæmic grower and doomed to an early death, for they do not appear a second season. There is no doubt that the open-shaped flower is far and away the better type. The variety Apogee is to my mind the ideal type—broad, overlapping segments standing at right angles to the tube. Dainty goes further and almost reflexes, and the segments are not broad enough. Apothéose, grand flower that it is, could be improved if it was a bit more open. The ideal flower must be large, have broad, overlapping segments, be of good substance, have good length and strength of stem and good scent. I do not care for the big, loose, narrow-segmented, flimsy flower. Mr. F. Herbert Chapman of Rye has, or had, a very good type of flower as regards shape. His variety Eldorado is one of this type, and though it might have more size, it is well worth growing for its shape and colour. For some reason I find the yellow varieties are the earliest to bloom. Buttercup and Goldfinch are followed by Daffodil and Treasure, with Apogee next. Golden King comes much later. I do not include any of my own raising not yet named or others not in commerce. Of these six varieties I put Daffodil first, followed very closely by Apogee. (I am not sure I shall not bracket them equal.) Daffodil is taller, deeper in colour, but not so open as Apogee. Treasure is early, tall and very large, but just fails in being rather cup-shaped, and its large flowers are apt to get top-heavy. Buttercup is inferior to these in size and shape. Goldfinch is the richest in colour, but is too small. Golden King fails in size and type of flower, but has a very rich colour, strong scent and a good stiff stem, and comes in when most varieties are over. Perhaps I shall find the perfect yellow in my seedlings—an Apogee flower with a Goldfinch colour, a Golden King scent, a Treasure for size, a Buttercup for earliness, and a Daffodil for length of stem!—G. H. DALRYMPLE.

SINGLE ROSES.

READING through the autumn numbers of THE GARDEN, particularly the Rose Number of November 5, I notice in the very interesting article on single Roses by the Rev. J. Jacob he states that singles have no class to themselves in the National Rose Society's Schedule. It is with great pleasure that I draw your contributor's attention to the class for single Roses as a table decoration. No Rose lends itself to the same light and graceful arrangement as these favourite single Roses. Compare their dainty growths and natural sprays of bloom to the walking-stick stems of Ophelia, which even at the summer exhibition of the National Rose Society's Show predominate in so many of the decorative classes. Many Rose lovers and exhibitors regret that there are not more classes for single Roses. What could be more attractive than a basket arranged with the glossy foliage of Mermaid and a glowing mixture of colour of Firelane, Irish Elegance, Mrs. Oakley Fisher, etc.? But the powers that be at the Rose shows say, "No, nothing but bowls and vases," filled for preference with specimen blooms. Why not the more decorative single Roses for the "decorative" classes?—(MRS.) L. COLSTON HALL.

THE SHOW PELARGONIUM.

ANYONE who has had to do with the culture of Show Pelargoniums, either for the purpose of exhibition or for home decoration, must be cognisant of the fact that they are anything but

popular to-day, and that in the schedules of many societies the competition became so small as to justify the elimination of a special class for such plants. The cause of this apparent lack of interest is not, I venture to say, due to any depreciation in the beauty of these old-fashioned flowers, but rather to misconception in some instances, and wrong treatment in others, of the requirements of these one-time favourite greenhouse plants. Unfortunately, so many have, perforce, either to grow Pelargoniums in a house where miscellaneous collections of plants are quartered or leave them out of their purview altogether. In nine cases out of ten they are grown, therefore, in a close overheated atmosphere—quite unnecessary for the plants under notice. This gives rise to trouble in the shape of green fly or red spider, which soon spreads to other plants in the house, and the offenders have to go. It seems to me a matter for regret that these showy flowering plants should have been allowed to drop out in many places mainly because of mistaken ideas as to culture. One may say of Show Pelargoniums that little heat indeed is needed, just enough to keep frost out during winter and dispel damp. Over-excitement produced by haphazard heating of the house and, not infrequently, dryness at the roots and absence of air are direct causes of the presence of the pests, which seem to spring from nowhere in the wake of these admittedly beautiful flowering plants. The keynote of successful culture in regard to them is coolness, and it is the ignoring of this which is responsible for so many failures. Visiting an exhibition on one occasion where prizes had been offered for "six plants for decoration," I noticed a solitary exhibit of Show Pelargoniums. The plants, remarkably clean and robust and full of flowers, indicated quite plainly that cool, rational treatment had been observed, and it was this which had undoubtedly been the means of the exhibit gaining premier honours.—W. LINDERS LEA.

THE LATE REV. W. WILKS, M.A.

THE world of horticulture has indeed sustained a loss by the sudden death of the Rev. W. Wilks. Though he passed away in the fulness of years, yet the end was very sudden, and few who heard him speak at the annual general meeting of the Royal Horticultural Society only a few weeks ago could have suspected that his course was so nearly run. The amount of work he did for the R.H.S. is difficult to measure. Not only did he act for many years as the Society's unpaid secretary, but he was also the unremunerated Editor of its Journal, which he was largely instrumental in raising to its present proud position. It was decided in 1912 that Mr. Wilks' twenty-five years' occupation of the post of secretary to the Society might fittingly be recognised by a presentation from Fellows of the Society who appreciated the work he had done. £611 was quickly subscribed, and Mr. Wilks was presented with a suitably inscribed salver and a cheque. Mr. Wilks, however, retained the secretaryship until the close of 1919, when he wrote: "Reconstruction requires a vigorous initiative, and that is always a weak point with old people. New projects are already presenting themselves—provincial shows, provincial branches, great developments at Wisley and other things are sure to arise before long. . . . It is well, too, that he who will have to carry out these undertakings should also have their initial organisation; and, on the other

hand, it may possibly be not altogether undesirable that the late secretary should, for a time at least, be at hand to explain matters to his successor and give him any help he may reasonably ask for."

This letter shewed the clear-sightedness which had distinguished his occupation of the secretarial chair. When, in 1904, schemes were brought forward to celebrate the centenary of the Society, the secretary set himself quietly to work to obtain the present hall and offices in Vincent Square, and also to find new gardens to replace the existing garden at Chiswick, which was fast becoming unsuitable for plant culture. That his efforts were successful is now a matter of history. The Royal Horticultural Society was all in all to him, and he maintained touch with it to the last. He was at the time of his death a member of the Council and of several Committees, some of which he attended as recently as February 27 last.

In 1893 he underwent a serious operation for throat trouble, and for a long time could only

THE LATE REV. W. WILKS.

speak in a whisper. As Vicar of Shirley for thirty-three years up to 1912 he did much to improve the village. Through his efforts a new organ chamber was added to the church in 1881. New church schools were built in 1885, and a workman's institute in 1886. In addition, he made Shirley famous as the home of the Shirley Poppy, surely as remarkable a result of patient endeavour as could be found anywhere! Few flowers have more claims to popularity. Equally beautiful as growing or when cut, enormously prolific and suitable for every garden—the smallest as the largest—it is indeed everybody's flower. A more lasting and beautiful memorial than this no one could desire. No medal that may be struck bearing his likeness and name can be as lasting a memorial as the flower he evolved with such patient labour. The Shirley strain of Foxgloves was another of his productions.

There are, alas! few men who are prepared to give the amount of disinterested work to any cause that the Rev. Wilks devoted to the Royal Horticultural Society, but his example might well be an inspiration to others.

WATER AND BOG GARDENING—IV

NOW we come to the question of plants for deeper water, where, too, space is generally more ample; and nature here has been even more lavish than in the case of the smaller growers.

In the *Nymphaeas* alone the choice is so wide that one is compelled to omit many exceedingly beautiful forms within the limits of one article. To begin with we have *alba*, the common white form that grows so lavishly in some of our quiet pools and backwaters; but this is not the best for garden purposes, *Mariacea albida*, an immense pure white with bronzy foliage, or *candidissima plenissima*, with large and almost perfectly double white flowers, both being preferable. *Aurora* is very good, with large deep orange flowers becoming more intense in colour every time they open and having to its credit the hall-mark of the first-class certificate of the R.H.S. *Caroliniana* is a robust grower with large coppery leaves and delicate pink flowers, with the added charm of fragrance. *Chrysanthia* is interesting for its handsomely marbled foliage and its pretty yellow flowers that become vivid vermilion as they age. *Colossea* is grand where plenty of room can be given to it, for its gigantic flesh-coloured flowers are borne in an uninterrupted succession, both early and late in the season. *James Brydon* is a variety of note, against which "most distinct" must be written, for the flowers are very large with broad petals of light pink, forming a really admirable flower. In the *Mariacea* section we have—in addition to *albida*, mentioned above—*earnea*, with beautifully mottled leaves and white flowers suffused with pink and *Chromatella*, one of the most beautiful of all hardy *Nymphaeas*, with bold marbled foliage and immense, nearly double canary-coloured blooms very freely produced. *Flammea* is reddish purple shaded with white; while *rubra punctata* is one of the largest—deep purple with bright orange stamens.

For the largest sheets of water, where the water garden becomes a lake of ornamental water, the *tuberosa* varieties are the most vigorous of all *Nymphaeas*, and increase at a speed corresponding to their vigour by means of tuberous offsets that are readily detached from the creeping rootstock. The foliage is coppery green and the flowers in the type are white, the outer petals being tinged with flesh pink. A variety of this, *Richardsoni*, is double

and pure white, the outer petals drooping so that the entire flower forms a perfect globe. Less vigorous than the two former is *tuberosa rosea*, a very beautiful thing which is similar in all respects

THE WATER ARUM, *PELTANDRA VIRGINICA*.

to the above, save that the growth is more restrained and the colour bright rose. *W. Falconer* is a hybrid of immense size, the flowers measuring 6 ins. or 7 ins. across, vivid crimson in colour, strikingly enhanced by the centre of the golden stamens. While young the leaves are reddish, becoming olive green with red veins as they mature; superb for the medium-sized pool.

Leaving the *Nymphaeas* again, we come to other plants that both float upon and grow through the water's surface. For shallow water at the margin the variegated Sweet Flag, *Acorus Calamus variegatus*, is simply splendid and far better than the type, for its beautifully striped pink and green and yellowish white leaves are ornamental through the entire season. *Alisma Plantago*, the Great Water Plantain, grows strongly erect to a height of 2 ft. or 3 ft., with large ribbed leaves and much-branched stems of white flowers.

For deep water *Aponogeton distachyon* is capital, with bright green oblong leaves floating on the water and long stems that end in a double spike of white bracts, with purple brown anthers and a hawthorn perfume. The Flowering Rush bears masses of rushy green foliage and, thrown well above this, strong bright pink flowers borne

on the top of a long stalk which reaches a height of 3 ft. or 4 ft.

For shallow water near the margin the Water Arum, *Calla palustris*, is an excellent counterpart of its common name. The foliage is green and the white flowers, followed by conspicuous seed vessels, are freely produced in early summer. The Bog or Buck Bean, *Menyanthes trifoliata*, is worth a prominent place where its bean-like foliage and attractive flowers, the segments of which are finely frimbriated on the inside, shew to great advantage. *Orontium aquaticum* or Golden Club is a space-filler, very vigorous, with velvety green foliage resting upon the water and club-like spikes of golden yellow flowers that rise 1 ft. above it. The Water Arum, *Peltandra virginica*, is capable of forming a most striking specimen with large arrow-shaped leaves and handsome white arum-like flowers. A big group of this is well worth while, being decorative all through summer. *Pontederia cordata* must not be passed by for margins, for it is a very free-flowering plant with large tufts of heart-shaped, erectly-growing leaves standing well above the water, and spikes of closely set blue flowers.

Where a gigantic foliage plant with upright stems that will grow in shallow water is required, note *Rumex Hydrolapathum*, the Water Dock, for in the mass it is very striking and effective, especially when the foliage turns scarlet in autumn. The Arrowhead exists in quite a number of varieties, among which may be mentioned *Sagittaria sagittifolia*, with white flowers with dark anthers, and *S. variabilis* fl. pl., a big group of which, with its arrowhead-like leaves and stems of double white flowers, is most effective. *Typha latifolia*, the Cat's Tail, a well known native of the riverside and fens, brings all its dignity with it when we import it into the large water garden and gives us splendid clumps of broad foliage and club-like heads on vigorous stems 6 ft. to 8 ft. high.

The lists are even now nothing like complete. One might add considerably if occasion required, but those mentioned should provide sufficient for any except the most extreme needs.

H. W. CANNING-WRIGHT.

WATERSIDE PLANTING, INCLUDING THE EFFECTIVE *ACORUS CALAMUS VARIEGATUS*.

THE NEWER VARIETIES OF ALLWOODII

MUCH progress has been made in the development of these useful, interesting and hardy plants, and the following newer introductions are worthy of consideration.

Alfred.—A pure white self. This novelty will eclipse the popular Harold, for it is a denser white and the blooms are fuller. It has a splendid erect habit and it is very floriferous.

Arthur.—Red maroon with a dark centre. This is a well-shaped flower with plenty of petals and a good calyx. It is of compact habit, short jointed and vigorous. It has the distinct central marking that Mr. Edward Allwood considers one of the most pleasing features of the Allwoodii and a characteristic that they would be sorry to lose.

Barbara.—A rich crimson self. It bears large, full flowers with a fringed edge to the petals. It has a strong habit and soon makes a shapely plant.

Betty.—White, with a red maroon centre. I consider this one of the daintiest of the newer varieties. It has a neat habit and makes an ideal plant for edgings.

Dickon.—Brick red with maroon centre. This is a particularly free-flowering variety and has a short-jointed habit. The flowers are carried in clusters.

Edith.—White with violet centre. A pretty variety with a good habit. The blooms are carried on long stems and stand erect above the foliage.

Eleanor.—White with crimson purple centre. A large double flower with fringed petals. This variety bears, in my opinion, the finest individual blooms of any yet raised. It has a splendid habit and the blossoms are carried on strong, erect stems.

Hugh.—Crimson purple self. Last season was not very favourable for flowers of this shade, as purple is a colour that spots in rain, but in a sunny year it should be grand. The individual blooms are large and well shaped.

Joyce.—Deep salmon pink with pale maroon centre. Lovely colouring is portrayed in this new variety, and it is very effective when used for room decoration. It has a free habit and the blooms are borne on erect stems.

Lottie.—Pale salmon self. A new and pleasing shade that will be in demand for decorative purposes. It is a double flower, rather loosely built and not unlike Jean in character.

Marion.—Another pleasing pink shade, nearly the same colour as Rose Dorothy Perkins. The flowers are of good form and have fringed petals. It has a good habit and the blooms can be cut with plenty of stem. A useful decorative variety.

Matty.—Reddish maroon with maroon eye. It has a short, dwarf habit and bears semi-double flowers with fringed petals.

Maud.—Pale rose pink with salmon flush. One of the most pleasing colours and invaluable for decorative work. It is very pretty in artificial light. The flowers are produced in clusters.

Nell.—Peach pink. A popular and pleasing colour. It is a strong grower and good for the herbaceous border.

Peggy.—Deep violet-maroon. A new self colour, free flowering and of quick growth. Flowers are of good form and fringed.

Rhoda.—Deep rosy mauve with crimson eye. A counterpart of Betty and equally useful for edgings.

Robin.—Brick red self. It has a strong habit and bears double flowers on long, erect stems, chiefly in clusters.

Sybil. Delicate flesh pink. A new colour break. Very beautiful for decorative purposes. Fine habit and flowers of perfect form, generally borne in clusters, on long stems.

Vera.—Blush pink. A little deeper shade than Sybil. The flowers are semi-double and have a smooth edge to the petal. It has a short, compact growth and is very useful for edgings.

NORMAN LAMBERT.

LIME AND ITS USES

DO amateur and professional gardeners, and others who till the soil, realise that lime is a very important, if not the most important, factor in successful cultivation? Like many other essentials to plant growth, science has been able to produce this soil constituent in a form helpful to plant life. Used in the right way and in the proper form, lime is not only an essential soil ingredient, but has considerable value as a fungicide, insecticide and effective dry spray, which is not generally realised. The uses of lime are manifold and the benefits to be derived from its application are really great.

Slaked or hydrated lime is, if pure, owing to its fineness, unquestionably the most valuable form for horticultural purposes, inasmuch as it will more quickly pass into solution. It is easily assimilated by the soil and thus readily stimulates plant life by making it possible for plant foods to be absorbed. Lime acts chemically, physically and bacteriologically in the soil.

It acts CHEMICALLY by hastening decay of organic matter or manures and setting free the elements of plant food they contain, and also by releasing the potash which clay and heavy soils usually contain and by rendering phosphoric acid more readily available for the plants.

It helps PHYSICALLY on a clay or heavy soil by coagulating the particles of soil and making them more granular, so that there is better drainage and greater warmth. It is a proved fact that one gets an earlier and a better tilth on heavy land that has been properly limed than where it has not been so treated. The density of a clay or heavy soil is due to the particles of soil being so fine that they hold moisture and bind together. Slaked or hydrated lime corrects this by making the soil more open and more friable and consequently easier to cultivate.

It is of value BACTERIOLOGICALLY by sweetening the soil and providing a congenial environment for the soil bacteria. The fertility of the soil is due to the action of beneficial bacteria converting the various elements present into such a form that the plant can take them up. In performing these functions the bacteria throw out a minute amount of acid and, unless steps are taken to neutralise this acidity, their surroundings are not healthy, the organisms languish, lose efficiency and eventually die off. Lime corrects this acidity and enables the bacteria to carry on their beneficial work.

As a FUNGICIDE lime in the soil is capable of materially lessening, if not preventing, many diseases, such as "Finger and Toe," "Club-root," etc., but in every case it should be applied to the surface soil so that the rain may wash it in. If applied more than 4 ins. to 6 ins. below the surface it is not so effective. A pure lime, correctly hydrated, used as a dry spray also lessens and prevents in many cases air-carried diseases, such as potato and tomato blight, also some diseases or pests which attack trees and plants, fruits and vegetables, whether under glass or in the open.

Lime, in many cases, is an effective INSECTICIDE. Its efficiency in this direction depends much on its fineness and purity, brought about by correct

hydration, for it is often quite possible to add too much or not enough moisture.

As a DRY SPRAY against caterpillars, through a suitable dry sprayer it chokes up the breathing pores and in most cases is a preventive against the many insect pests which attack vegetables, fruits or flowers, and is generally acknowledged to create healthy foliage and growth. Lime is well known for use against slugs, but it is not generally known that the slug has the power of exuding a slime which enables him to escape from the first powdering his body receives, but a second application within a short space of time is beyond his powers and generally destructive.

It is not only a waste of money to apply fertilisers to land deficient in lime, it is positively harmful, in that the soil is being made more acid. The elements that fertilisers contain are not available as plant food unless there is lime present to set them free and they cannot become free otherwise. Sulphate of ammonia is very destructive to lime in the soil, and where frequently used liming should on no account be neglected; the same destruction obtains where super-phosphate is used. Nitrate of soda is also much more effective where lime is present in the soil. This applies to cultivation outdoors and under glass.

LIME varies as much as coal as regards quality. When one buys ordinary or lump lime one always buys something else besides. This something else may be silica (sand) or alumina (clay), or what is worst of all for horticultural or agricultural purposes, magnesia. This is usually present in most soils in sufficient quantity for all ordinary purposes and is perhaps a more important constituent in soils where Vines are grown. For horticultural purposes lime should, in the opinion of the writer, contain no more than 2 per cent. of magnesia (less than 1 per cent. is preferable) and there are some limes on the market which contain up to 40 per cent.

CHALK, which is frequently used, is slow in its action and does not possess the sterilising action of lime burnt in the kiln. Moreover chalk frequently contains an excessive amount of moisture and is usually dried before it is sent out as a dry powder. If the chalk has contained 20 per cent. to 25 per cent. of moisture before being dried, it will, of course, take up just the same amount of moisture when applied to the soil, and there is the possibility of its becoming pasty, which makes even distribution in the soil impossible. In this state it may cake and thus prevent the proper aeration of the soil.

Buxton is acknowledged to possess the purest deposits of limestone in the world. The burnt stone yields up to 98.40 per cent. pure lime (CaO). This lime possesses the physical property of breaking up into a finer state of division than any lime yet known. This lime may be obtained scientifically hydrated and, in appearance, just like flour. This product is known under the proprietary name of Limbux. Pure lime may cost a little more than an inferior article, but it costs no more to distribute and a smaller quantity may be far more effective in the soil, besides its efficiency for use as a dry spray, as a fungicide and as an insecticide, a safeguard against many diseases and insect pests.

It can be applied to fruit trees, etc., in bloom without scorching or doing any damage, in fact, it appears to assist pollination. Are fruit trees and the soil they grow in sufficiently limed? There is much to favour the use of lime in conjunction with Narcissus or Daffodil growing as a safeguard against Narcissus diseases and, perhaps, eelworm. Most vegetables benefit by lime, so also do Begonias, Carnations, Gladioli, Chrysanthemums, Sweet Peas, Roses, etc. Tennis courts, golf greens and lawns would all produce finer grasses by applications of suitable lime at intervals. Without lime, soils cannot produce good crops, not forgetting that

"Lime and lime without manure will make both land and grower poor." Besides being constantly absorbed in neutralising the acid products of the soil, lime is removed from the soil by the action of rain or drainage in England, Scotland and Wales at the rate of approximately 500lb. per acre

annually, but the amount used by the crop is small in comparison. Unless the wastage is made good from time to time, the soil, however "good in heart," cannot possibly be so productive as it should be.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Vegetable Marrows.—For an early supply a few seeds of one of the small-fruited varieties should be sown in pin pots and placed in a warm greenhouse. A hot-bed and box frame will be necessary when the plants are large enough to put out. A heated brick pit is also suitable. Plants for outside should be raised a few weeks hence.

Winter Greens.—Under this heading the average gardener includes all the green vegetables that are in use during the autumn and winter months, and, collectively, they constitute an important lot. The site for the seed-bed having been dug some weeks previous, will only need raking down, then shallow drills should be drawn 1ft. apart. When the seed is sown it will be advisable to cover the bed with netting to protect the seeds from birds. The turnip fly is often troublesome, and, just as the seedlings are appearing through the soil, it is a good plan to dust the lines with soot, lime or fine grit. Such work ought to be done while the morning dew is still on the plants. In many gardens it is desirable to have Cauliflowers or Broccoli all the year round, and to this end several varieties are grown. Among the Cauliflowers Veitch's Autumn Giant and Early Giant are both reliable; while Broccoli should be represented by Michaelmas White, Early White, Leamington and Model. Savoys Drumhead and New Year; Kales, Scotch and Favourite; Purple and White Sprouting Broccoli, and Cabbage All Heart.

Hoeing.—However well the garden is kept, weeds will appear, and it is always policy to catch these in the seedling stage. Use the hoe freely not only to destroy weeds, but to loosen the surface soil, and thereby benefit the crops.

The Flower Garden.

Annuals.—Among annuals will be found a host of beautiful flowers, all of which are of easy culture, and many should be sown where they are intended to flower. Among the more recent introductions the fine varieties of *Eschscholtzia* should certainly be given a trial. The gentian blue *Phacelia campanularia* is a gem, a dwarf, compact-growing plant which ought to be sown in the open. A few annuals, such as *Phlox Drummondii*, *Mimulus*, *Nicotiana* and *Zinnia*, are best sown in boxes of light soil and raised in a warm greenhouse, pricking off the seedlings in a cold frame or boxes when they are large enough. Such annuals as Stocks, Asters, Clarkias, Larkspurs and Marigolds I sow in a cold frame, and obtain excellent results. The plants are sturdy, and, if the seeds are sown thinly, the pricking off process is dispensed with the seedlings being transplanted to their permanent quarters when the weather is suitable. Anyone who has not yet tried the single-flowered varieties of Aster should include a few this year; they are showy, and first-rate for cutting purposes.

Border Carnations.—If the layers were potted up last autumn, and have been accommodated in a cold frame, they should now be planted out in beds and borders. In these days Border Carnations are so good that they deserve a piece of ground that has been well prepared. Old plants of the perpetual-flowering type will furnish quite a lot of flower if planted out when they are of no further use inside.

Vegetables Under Glass.

Tomatoes.—If seeds were sown as advised in this column in the issue dated January 20, page 38, the plants will be large enough for the pots in which they are to fruit. The roots should be placed rather deep. The soil should consist of fibrous loam three parts and one part from an old mushroom-bed or horse droppings. A sprinkling of bone-meal should be added, and then the whole well mixed. A few inches of space should be left in the pots for top-dressing later on. Where possible the plants should be put out in borders

in the house. A foot depth of soil would be ample; in fact, they can be grown successfully with less soil. Much will depend on the structure, but planting out is the best method; better crops are secured and less labour is needed to keep the roots supplied with water. Unless the plants can be carried on strings to overhead wires or other supports, each one will require a stake, which must be strong, or the weight of the fruit will bend it over. Tomatoes may be grown in pits and deep frames, which will be available in due course. Seeds may now be sown for this purpose and to produce plants for growing outdoors.

The Hardy Fruit Garden.

Grafting.—Where inferior varieties of Apples and Pears exist, they may be replaced by grafting, but unless one has had experience in this operation it is better to employ outside help. This is the time for the work.

Strawberries.—Remove all decayed foliage and weeds, and then give the soil a thorough hoeing. Afford a dressing of soot and a sprinkling of some fruit manure. Afterwards clean straw may be placed between the plants whenever an opportunity occurs.

Insect Pests.—Examine Gooseberries and other bush trees for caterpillars and green fly, and if present, spray with a reliable insecticide. If gooseberry mildew is in the district, spray the trees a few times during the growing period with Bordeaux mixture. It is useful as a preventive.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),
Castleford, Chapstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Autumn-Sown Onions.—Except on light soils where they are apt to be uprooted by frost, autumn-sown Onions give excellent results. It is a good plan to thin them out and transplant as many of the thinnings as are likely to be required, and this should be attended to within the next week or two. Onions delight in a rich soil. Those that are allowed to remain should be given a dressing of some reliable artificial manure, such as nitrate of soda or guano, to set them into active growth. Onions sown under glass during January should now be gradually hardened off preparatory to being planted out.

Asparagus.—The top-dressing the beds received in autumn should now be forked in. A light dressing of salt prior to starting the operation will be of considerable benefit, as Asparagus is a salt-loving plant.

Lettuce.—A sowing of Tom Thumb or other small, quick-maturing variety may now be made on a warm border to succeed those grown under glass.

Peas.—Another sowing should now be made, and for this purpose it is advisable to rely on a second-early variety, such as Senator or Royal Salute. Continue to make sowings of Spinach between the rows.

Vegetables Under Glass.

Cucumbers.—If seed was sown in good time, Cucumbers will now be ready for planting out. Where there is no special house for them a plant or two may, as a makeshift at this early season, be grown at the cooler end of the melon-house. Those who depend upon frame culture should be securing a supply of fermenting materials with a view to planting next month.

Tomatoes.—Where seed was sown during December or early January the plants should now be ready for their fruiting quarters. There are three systems practised, viz., planting on the floor of the house and training the plants to vertical strings, planting in a raised bed and training the plants on a trellis like Melons or Cucumbers, and growing them in pots gins, to 2ins. in diameter. Where only a moderate quantity is grown either of the two last-mentioned

systems is to be recommended. Good fibrous loam with the addition of some bone-meal or bone-flour should be used. Maintain a buoyant atmosphere with a temperature ranging from 55° to 60°.

Fruit Under Glass.

Melons. Seeds for the main crop may now be sown singly in small pots in bottom-heat in a temperature of from 60° to 65°. Among green-flesh varieties Diamond Jubilee can be recommended with confidence, as can Sutton's A 1 among scarlet flesh varieties.

Peaches.—As soon as the fruits attain the size of small marbles the work of thinning should be taken in hand. It is a great mistake to over-crop the trees, as it is bound to militate against their future welfare. A good general rule is to allow 1ft. between the trunks; thin gradually.

The Flower Garden.

Mignonette.—Although perfectly hardy, it is a good plan, where really fine spikes are desired, to sow the seed under glass either in small pots or in boxes, as is done with the ordinary run of half-hardy annuals.

Sweet Violets in frames should now be encouraged to develop a certain number of runners to furnish stock for planting out next month. Ventilate the frames freely back and front, and as evaporation will now become more rapid, care must be taken that the plants do not suffer from lack of water.

Violas.—If the ground is ready for their reception and the state of the weather permits, Violas should be planted out. There is a decided advantage in planting early, as they have then time to get thoroughly established before the heat of summer sets in, when late-planted stock is apt to suffer and even to die off.

The Hardy Fruit Garden.

Protecting Stone Fruits.—As soon as the trees on walls come into flower a watch must be kept for threatened spring frosts, and the trees should be protected by suspending some light protecting material in front of them. Tiffany or even a double fruit net will generally prove quite sufficient for the purpose.

CHARLES COMFORT

(Formerly Head-gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Chinese Primulas are as a rule thrown away after flowering, but they make fine large specimens if grown on for the second year. Where it is desired to grow them on in this way, good healthy plants should be reserved after flowering. They need not be repotted until some time during May, when they should have a shift into 6in. or 7in. pots, taking care to pot them well down, as they will then throw out fresh roots from the stem. Grown on in this way the stellata varieties make very fine specimens, although any of the varieties may be treated in the same way. Another way of producing large plants is to sow the seed during August or September, growing the subsequent plants steadily on for about fifteen months before they are allowed to flower. The old double white *Primula*, which is so useful for cutting and for making up in floral arrangements, has to be increased by cuttings or division. The plants may be shaken out of their pots and divided, putting them into small pots, and, if stood in a propagating case with slight bottom-heat, will soon make fresh roots. Another method of increasing them is to trim off some of the bottom leaves and mound up the stems with leaf-soil and sand to which a little chopped sphagnum may be added. When the plants have made fresh roots into this mixture they may be divided and placed in small pots, keeping them close for a few days until the roots get a hold of the fresh soil, afterwards potting them on as they require it. All *Primulas* of this class are best grown in low pits well up to the roof glass or in cold frames during the summer months.

Impatiens Balsamina.—An early sowing may now be made in an intermediate temperature. The seed should be sown very thinly, as the young seedlings draw very quickly if at all crowded. When they are potted off they should be buried up to the seed leaves, as they root out from the stem. The plants should not be given too much heat or else they will become weak and drawn, and as the season advances they should be grown in a quite cool house.

Impatiens Sultani and I. Holstii.—Seed of these plants may also be sown at this time. These kinds are very useful for furnishing the greenhouse,

as they remain in flower all the summer. Any good colour varieties of *L. Holsti* should be propagated by means of cuttings.

Impatiens Oliveri is very useful for the conservatory, as fine large specimens can be grown in tubs. It may also be planted out in a bed in the conservatory. This beautiful plant should be more generally grown, as it remains in flower more or less all the year round.

Chrysanthemums.—Cuttings for small pots should now be taken either from old stock plants or else taken from the tops of young plants rooted some time ago. This latter method is probably the best, as the young soft wood makes much freer growth. The cuttings should be rooted under quite cool conditions, so as to ensure strong and sturdy plants from the beginning. The plants should not be allowed to suffer from lack of repotting at any time; they should also be pinched frequently to induce a bushy habit. As they are flowered in 6in. or 7in. pots, they require strict attention as regards watering during all stages of their cultivation. The aim should be to retain throughout good foliage right down to the pots. For the purpose in view varieties should be selected that are naturally of a dwarf bushy habit. All the forms of *Caprice du Printemps* type are excellent for this purpose. Some of the smaller-flowered single varieties are also very beautiful and, although by no means new, *Lady-smith* is still one of the best.

Schizostylis coccinea. The Kaffir Lily, although hardy if grown in a warm border in front of a greenhouse in the south and west, is well worth growing for pots, as it produces its flowers during autumn and early winter. For this purpose it is best grown outside in a bed of rich soil during the summer months. They should be divided into single crowns, which may be planted in lines, placing them 6ins. apart in the lines, or six to eight strong crowns may be planted together in a clump. In the autumn such clumps may be lifted intact and placed in 6in. pots. They remain in flower for a long time in a cool greenhouse.

Royal Botanic Gardens, Kew. J. CORTIS.

The Rocky Mountain Columbine.—It would be difficult to name a Columbine which is quite so attractive as *Aquilegia cœrulea*. It also possesses the merit of being distinct, the perfectly upright poise of the flower at the head of the stem being a characteristic almost unique among its kind. This very lovely species is of somewhat slight growth, yet quite rigid and erect. The comparatively scanty, glaucous foliage, small-leaved and delicate, is mainly gathered about the base of the flowering stem, which latter ascends to the height of about 1ft. The long-spurred blossoms are very large, creamy white in the centre, the remainder being a good firm blue with perhaps the slightest hint of cool lavender to complete a most delightful tone. These flowers open early (before most others), and this is a matter of no small moment, since it ensures a crop of true seed, which is a boon to many who have to treat *A. cœrulea* as a biennial. This plant, however, is by no means always difficult. It is often quite permanent in gardens where it can be afforded a gritty, or even stony, soil with some leaf-mould. But while it must not be too sodden in winter, it undoubtedly enjoys a cool root-run, such as a rock garden ledge sloping to the north west might afford. Seed germinates quite freely and the young plants give no trouble.

The Ghent Flower Show.—Mr. John Weathers of Park View, Isleworth (who has been invited for the sixth time to serve on the International Jury in April this year) will be pleased to hear from other British members of the Jury and others, so as to make up a party of twenty-five or more. If communication is made in good time, it may be possible to get all the British members into one hotel, and to arrange for a visit to the various nurseries round Ghent and Bruges, and also, perhaps, to make a flying visit to some of the scenes of the Great War. Mr. Weathers was over this ground two years ago, and knows Belgium

pretty well. Enquiries to the address given above should be accompanied by a stamped directed envelope.

Roses at Wisley in 1923.—The Director of Wisley would like to remind those who intend sending Roses for the R.H.S. Rose trials at Wisley that the last day on which they can be accepted is Saturday, March 31. He will be pleased to send the necessary entry forms on receipt of a postcard addressed to The Director, R.H.S. Gardens, Wisley, Ripley, Surrey.

Trials at Wisley. The Royal Horticultural Society will carry out a trial of Wallflowers and Sweet Williams during the coming season. One packet of each variety for trial should be sent so as to reach the gardens by April 30 and addressed to The Director, R.H.S. Gardens, Wisley, Ripley, Surrey (goods via Horsley Station, Southern Railway). The necessary entry forms may be obtained on application to the Director. They will also carry out a trial of summer-flowering outdoor Chrysanthemums during the ensuing season. Three plants of each variety for trial should be sent so as to reach the gardens by April 30 and addressed to The Director at the above address. The necessary entry forms may be obtained on application to the Director.

FORTHCOMING EVENTS.

March 20.—Winchester Horticultural Society's Meeting.

March 21.—Wimbledon Gardeners' Society's Meeting.

March 22.—Royal Botanic Society's Meeting.
—Wargrave and District Gardeners' Society's Meeting.

Answers to Correspondents THE GREENHOUSE.

THE TREATMENT OF GERBERA JAMESONI HYBRIDS (L. B. Berks).—The flowers of the Jamesoni hybrids have varying shades of orange-scarlet. The plants may be wintered in a temperature varying from 40° to 45°. In the summer-time a cool position in an unheated and well-ventilated greenhouse will be suitable. No difficulty need be experienced in growing the plants in a cold frame if the structure is deep enough. Much shade makes the flower-stems still more weakly. A suitable compost is one of good loam two parts, leaf-soil one part and well rotted manure one part, with a free sprinkling of coarse sand.

CAMELLIAS ATTACKED (T. A. P.).—The plants are attacked by the scale insect, *Pinnularia camellicola*. They should be thoroughly cleansed by washing and sponging, removing the insects with a blunt stick and using Gishurst Compound at summer strength or a wash made by kneading flowers of sulphur into a handful of soft soap and dissolving it in 1½ gallons of water. If the insects reappear, spray, as soon as they are seen, with a nicotine soap solution that has often been recommended in these columns.

SOLANUMS (W. W. Weybridge).—Our correspondent does not say what sorts she is growing. If *Solanum capsicastrum*, with orange-scarlet fruit, the plants should be partly pruned back when starting into growth. They should have the balls of soil slightly reduced to allow of them being repotted into the same-sized pots, giving them a shift later on if required. They may be planted out for the summer, when they make fine large plants, which can be lifted and placed in pots during September. Propagation may be carried out by means of seeds or cuttings at any time during the spring, but if good plants are required the same season, they should be propagated during January.

MISCELLANEOUS.

DESTROYING TREE STOOLS (F. H. S. Andover).—A stool can be killed to prevent the production of suckers by boring five or six holes 9ins. to 12ins. deep just inside the bark. Fill these with liquid weed killer and plug the holes with wooden pegs. Salt-petre is often recommended in text-books, but it is uncertain in use and slow at the best. Whenever possible the trees should be grubbed. In felling the butt is then lifted out of the hole. Once out of the ground it can be blown to pieces with gunpowder or rolled to a suitable position and covered with ivy.

NAMES OF PLANTS.—F. E. Kent.—*Billbergia nutans*, "Maui Poppy."—*Lonchocarpus Standishii*.

CATALOGUE RECEIVED.

New Seedling Pyrethrum

EILEEN MAY ROBINSON,
A.M., R.H.S., June 7th, 1922 (Votes unanimous).
The finest and most beautiful single pink Pyrethrum ever raised. A superb variety for the border or cutting.
3/- each; 30/- per doz., post free.

SPECIAL COLLECTION, all grand plants, 10/-, post free.
Eileen May Robinson, Queen Mary, Snow White, Aphrodite, James Kelway, Mrs. Bateman Brown, Stewart Clarke, J. N. Tweedy, La Neige, Firefly, Wilson Barrett and Benedict.
Standard varieties, 8/- per doz., post free.

H. ROBINSON,
Nurseryman and Florist, BURBAGE, HINCKLEY.

"How does he manage it?"

you ask. "My garden doesn't look like that."

You wish it did. Well, but you use ECLIPSE Fish Manure?

It isn't sufficient to buy the best seeds and cuttings. They won't grow on poor ground. You can't expect to get A1 results out of a C3 soil.

A weak soil gives no nourishment to plants. Strengthen it. Enrich it with ECLIPSE Fish Manure, and you will get more and better blooms—hardy plants, deep rich-coloured flowers—month in, month out.

ECLIPSE Fish Manure contains Phosphates, Nitrogen and Potash in their proper proportions. Being largely organic, it supplies humus to the soil.

PRICES:

7lbs. 14lbs. 28lbs. 56lbs. 112lbs.

SCOTCH SEED POTATOES

Our stocks are grown and selected specially for Seed purposes, and under normal conditions of soil and situation, cannot fail to produce first-class crops. All are Class I. Scotch, Immune varieties certified by Board of Agriculture. Bags free. Keenest prices. Write for Catalogue.

NEW VARIETIES.—Catriona, Di Vernon, Katie Glover.

FIRST EARLIES.—America, Arran Rose, Eclipse, Edzell Blue, Epicure, Immune Ashleaf, Midlothian Early, Sharpe's Express, Victory, Witch Hill Early.

SECOND EARLIES.—Arran Comrade, British Queen, Great Scot, K. of K., King George, Nithsdale.

MAINCROP.—Abundance, Arran Chief, Arran Victory, Bishop, Crusader, Golden Wonder, Kerr's Pink, King Edward, Langworthy, Lochan, Majestic, Rhoderick Dhu, Tinwald Perfection, Up-to-Date, White City.

AUSTIN'S GOLD MEDAL GARDEN SEEDS
Descriptive Catalogue of all varieties of outstanding merit free on request. Write for copy.

Orders have prompt attention.

AUSTIN & McASLAN,
89-95, Mitchell Street, Glasgow.

Established 1717.

KILL those WEEDS!

You can destroy weeds with Weedicide—clear the garden paths, drives, etc., and do it quickly with the weedkiller that has been "commended" by the Royal Horticultural Society.

WEEDICIDE

1 Gall. (price 9/-) dilutes to 100 Galls. water, the cost of the ready-for-use weedkilling mixture is, therefore, just over 1d. per Gallon.

1 pt. tin 2/-, 1 qt. 3/3, ½ gall. 5/6.

OTHER COOPER SPECIALITIES.

FUNGICIDE.

The IMPROVED Bordeaux Mixture for Potato Disease, Apple and Pear Scab and other fungoid diseases.

1 lb. tins 1/-, 5 lb. tins 3/6, 10 lb. 6/-
—Larger quantities at reduced rates.

TOMARITE.

Non-poisonous tomato spray for Tomatoes. Remedy and preventive of fungoid diseases of external origin. Does not mark the fruit.

1 gall. (price 14/6) makes 200 gallons of spray mixture. 4 pt. tins 1/8. 1 qt. 5/-
Special prices for larger quantities.

CARROT AND ONION FLY DRESSING.

A Special Powder for minimising damage to growing crops from attacks of Carrot and Onion Flies.

13 lb. packets 1/-, 7 lb. 2/-, 14 lb. bags 3/-, 56 lbs. 9/6, 112 lbs. 17/6.

WM. COOPER & NEPHEWS LTD.,
BERKHAMSTED.

Popular Hardy Flowering Plants and Alpines

FOR PRESENT PLANTING.

We offer a large stock of well-grown plants, including specially good value in the following:—

		each doz.		CHOICE ALPINES—continued.		each	
Anchusa Opal	Beautiful pale blue	6d.	4/6	Convolvulus Cneorum.	A very choice Rock Garden shrub; rare	1/1	2/6
Anemone japonica.	Single white	6d.	5/-	Dianthus cæsius		9d.	9d.
Aquilegia.	A charming mixture of long-spurred hybrids	6d.	4/6	Draba bruniæfolia		9d.	9d.
Asters (Michaelmas Daisies)	in 12 good varieties	6d.	4/6	Dryas octopetala		1/-	1/-
Bellis perennis fl. pl.	Crimson Double Daisy	3d.	2/6	Geranium sanguineum lancastriense		9d.	9d.
Boltonia asteroides.	Late flowering white	6d.	5/-	Gypsophila repens		9d.	9d.
Campanula persicifolia alba		6d.	5/-	Helianthemum Red Dragon		9d.	9d.
Cheiranthus Allionii.	Brilliant orange	6d.	4/-	Helichrysum bellidioides		9d.	9d.
Chelone barbata.	Brilliant scarlet spikes	6d.	5/-	Hieracium villosum		9d.	9d.
Chrysanthemum maximum (Moon Daisy).	6 large flowered varieties	6d.	5/-	Hypericum fragile		9d.	9d.
Forget-me-nots.	Royal blue	—	2/-	Leontopodium alpinum (Edelweiss)		1/-	1/-
Erigeron Quakeress.	Pale lavender blue, flowers over a long period	6d.	5/-	Linum arboreum		9d.	9d.
Gaillardia grandiflora.	Showy yellow and crimson	6d.	4/-	Lithospermum purpureo-cæruleum		9d.	9d.
Gypsophila paniculata (Gauze flower)		6d.	5/-	Lychnis Viscaria splendens plena		1/3	1/3
Heuchera brizoides gracillima		3d.	4/6	Morisia hypogæa		9d.	9d.
Honesty		3d.	2/6	Phlox setacea Newry Seedling, mauve		9d.	9d.
Linum perenne.	The beautiful blue Flax, most charming	6d.	5/-	Plumbago Larpenæ		9d.	9d.
Lupinus polyphyllus.	New hybrids in various colours	6d.	5/-	Potentilla Miss Willmott		9d.	9d.
Phloxes.	Finest named	8d.	6/-	Raoulia australis		9d.	9d.
Phloxes.	Good mixed from named varieties	6d.	4/6	Saxifrage—a choice selection:		9d.	9d.
Pinks Mrs. Sinkins.	The large-flowered white favourite, strong bushy plants	6d.	4/-	Aizoon rosea.	Pink encrusted	1/3	1/3
Sweet Rocket.	Extra fine plants	4d.	3/-	Cæcia of Oxford.	White encrusted	1/3	1/3
Pinks Allwoodii (Perpetual Pinks) as under:				Cherry trees.	Pale yellow	9d.	9d.
Albert.	Pink with deeper centre.			Bathoniensis.	Crimson mossy	9d.	9d.
Robert.	Old rose, maroon centre.			Oppositifolia.	Pink (50 varieties in stock.)	9d.	9d.
Susan.	Deep pink, crimson centre.			Sedums—a choice selection:		9d.	9d.
Harold.	White			Ewerii.	Pink	8d.	8d.
Phyllis.	Deep pink.			Dasyphyllum.	White and pink	8d.	8d.
Strong young plants from pots		1/-	9/-	Kamtschaticum.	Golden	9d.	9d.
Papaver (Oriental Poppies).	Named, beautiful colours	8d.	6/-	Middendorffianum.	Yellow	9d.	9d.
Pyrethrums (French Marguerite).	Single to name	6d.	5/-	Spathulifolium purpureum.	Bright yellow	9d.	9d.
Pyrethrums.	Double to name	9d.	7/6	Spectabile brilliant.	Rich crimson (25 varieties in stock.)	1/-	1/-
Scabiosa caucasica.	A charming flower for cutting, delicate soft mauve	9d.	7/6	Sempervivums.	A choice collection of 6 varieties for	4/6	4/6
Solidago Golden Wings.	Showy, tall growing plants for background	6d.	5/-	Silene acaulis		9d.	9d.

THE BARNHAM NURSERIES, Ltd., BARNHAM, SUSSEX

The ATCO MOTOR MOWER

The most efficient Mower on earth.

It is no uncommon thing for ATCO owners to tell us that they have run their ATCO Motor Mower throughout the entire season without needing to adjust so much as a loose nut. Such experiences bespeak perfect craftsmanship in manufacture and assembly, and are evidence of the ATCO's smooth, simple, efficient working.

The ATCO TURF CULTIVATOR

(illustrated) aerates the roots, destroys plantains, daisies and other fleshy-leaved weeds, levels turf, loosens and collects moss, makes coarse grass fine. It can be affixed only to the ATCO Motor Mower.

Send for FREE BOOKLET offering FREE DEMONSTRATION on your own Grass, and furnishing many unsolicited testimonials.

CHAS. H. PUGH, Ltd.

Whitworth Works,

31, Tilton Road, BIRMINGHAM

A FEW APPRECIATIONS.

"The Lawn Mower which you supplied me with two years ago has just completed its second season's work without a single breakdown, and without me having to spend a penny on it."

Robert Noble, Esq.

"I enclose two photographs taken on my lawn. The child, aged twelve, can mow the lawn quite easily. I consider the machine is excellent."

E. Liebert, Esq.

"The Atco is working perfectly. I work it myself, and find the work quite a pleasure. It is done in half the time of the old pony mower, and the lawns have never looked as they do now."

Mrs. Dorothy Coppen.

Carriage Paid on 15/- orders and upwards.

BENTLEY'S EARTHWORM DESTROYERS (Liquid and Powder)

Prevents the formation of Worm Casts.

For complete Illustrated Catalogue apply to the Sole Manufacturers:

JOSEPH BENTLEY, Limited,
Chemical Works, BARROW-ON-HUMBER, HULL.

BEAUTIFUL VELVETY LAWNS

That is how they are often described in novels, but how seldom do they come up to the ideal? Instead of being "velvety" they are often brown or patchy and full of weeds. What is the remedy for poor lawns? Many things contribute, such as mowing, rolling and weeding, but the most important point is to regularly manure your lawn with a suitable Grass Manure, and the very best preparation for the purpose is

PEARSON'S

ANTI-CLOVER MANURE

which will discourage the growth of clover and weeds and will encourage the finer grasses.

LADIES' FIELD FASHIONS

The Ideal Dress Journal for the Modern Woman

Every issue of "Ladies' Field Fashions" presents the newest season's modes adapted to the needs of the smart woman of to-day. Prominent Fashion Artists picture in terms of simplicity and smartness the latest creations from the acknowledged centres of fashion, whilst style experts advise authoritatively on all matters of dress. An exclusive feature every month is a beautiful Colour Supplement picturing a variety of charming and wearable styles.

Published 26th of every Month - - PRICE 1 -

THE WORST OF ORCHARD PESTS,

Psylla Mali (Apple Sucker), the tiny insect which attacks and destroys opening apple blossom buds, will shortly make its appearance. Nico Soap is the remedy and stocks should be procured at once. There is nothing so good as Campbell's English-made Nicotine Insecticides for destroying all sucking insects.

CAMPBELL'S ENGLISH NICOTINE, 95-98 per cent. guaranteed, prices on application.

CAMPBELL'S NICO SOAP (Nicotine Soap). The best Potash Soft Soap, plus 7½ per cent. Nicotine, unrivalled for syringing or spraying. Prices—½ lb., 2/-; 1 lb., 4/-; 10 lb., 32/-.

CAMPBELL'S NICOTINE VAPORISING COMPOUND. Nicotine content, 50 per cent. Prices—10z., 1/6; 40z., 3/9; 80z., 7/6; ½ pint, 9/-; 1 pint, 17/6; ½ gallon, 61/-.

CAMPBELL'S NICOTINE FUMIGATING ROLLS, very simple and effective. In four sizes, for 500, 1,000, 2,000 and 3,000 cubic feet. Prices—7d., 10d., 1/6 and 2/- each.

CAMPBELL'S PATENT SULPHUR VAPORISER. The best method of exterminating Mildew from plants in greenhouses. In two sizes, for 5,000 and 10,000 cubic feet. Prices—18/- and 20/- each.

CAMPBELL'S LEMON OIL INSECTICIDE, splendid for sponging, dipping, or syringing stove and greenhouse plants. Pints, 2/3; quarts, 3/10; ½ gallon, 6/10; gallon, 12/- each.

CAMPBELL'S WEEDKILLER. One gallon makes 51 gallons for use. Per gallon, 7/-; 2 gallons, 13/-.

Obtainable from Seedsmen or, in case of difficulty, direct from the Manufacturer,

J. D. CAMPBELL, Nicotine Manufacturer,
LUND STREET, CORNBROOK, MANCHESTER.

MOISTURE-LOVING IRISES

PERHAPS on account of that beautiful wildling, the Yellow Flag, *Iris Pseud-acorus*, which is really an aquatic, the majority of gardeners have, at any rate, a tendency to regard Irises in general as aquatics or, at least, as partial to cool, moist soils. This is, of course, a quite erroneous notion. There are, as a fact, far more Irises which resent wet ground than those which approve of it. Even of those which love moisture there is none other in cultivation in this country which is an aquatic in the sense that *I. Pseud-acorus* is.

Iris sibirica and the nearly related *I. orientalis* will tolerate a good deal of flooding either in winter or summer, but they grow and look healthy in very ordinary border soil, and the mortality of this plant in nurseries owing to the great drought of 1921 was probably lower than that of almost any hardy plant which normally likes "the good things of life." It certainly stood up to the drought in the border when herbaceous Phloxes wilted and died. It will be seen, then, that the Siberian Iris is a very accommodating plant; one has only to add that it is an exceedingly beautiful one to appreciate that it should be found in almost every garden. There is now quite a number of named varieties, many of them obtained by crossing this species with *I. orientalis*, but with one exception—shortly to be referred to—there is none so effective as a good form of the typical plant. With this the flowers are comparatively small but a good number is produced on each stem and the scapes are carried high and gracefully and the colouring is a pleasing rich blue-purple. There are, unfortunately, poorly coloured forms about and some which, while fairly good as regards colour, do not flower as freely as

they should. Fortunately, the best type does not appear to deteriorate at all from seeds, at least if the plant is kept away from mongrel forms. There is a white variety or what passes for one; it is really a dingy cream colour and should be avoided. The bright mid-blue variety called Perry's blue is, however, worthy of all praise. It associates well with the type-plant.

Iris orientalis has been referred to as closely allied to *I. sibirica* and liking similar conditions, but it is in appearance quite dissimilar. The foliage is much broader—that of *I. sibirica* is quite grass-like in appearance, but not in texture—the flower-scapes are flattish and unbranched, the stems are not so tall and the individual blossoms larger. The best coloured form is called sanguinea on account of its crimson bracts. *Iris orientalis* Snow Queen is a beautiful white Iris, however, just as superior to the white form of *I. sibirica* as the typical Siberian Iris is to the typical *I. orientalis*.

Very similar as to their requirements, except that they will not tolerate real drought, are the giant Flag-like species *aurea*, *ochroleuca* and

Monnieri, and the hybrid forms known as *ochro-aurea* and *Mon-aurea*. These are stately plants, valuable for their foliage effect if they never flowered. They are by no means prolific of blossom, yet under proper culture they flower with sufficient freedom to make a beautiful picture. *I. aurea* has, as its name would imply, golden yellow flowers. *I. ochroleuca* has rather more slender foliage and the flowers are creamy white with a conspicuous yellow blotch on the fall. The finest form of this Iris is called *gigantea*; the blossoms are larger, but the plant is no taller than the form we regard as typical. The hybrid *I. ochro-aurea* is almost exactly midway between the two species in colouring, and very pleasing on that account, but it does not seem to flower so freely as either kind. *I. Monnieri* is a beautiful fragrant late-flowering Flag, the blossoms of which are rich yellow, margined white. Though obviously near akin to the other two species, it is quite distinct in foliage and flower.

From two moisture-loving species, *I. levigata* and *setosa*, has been evolved the strain of Flag Irises known in gardens as *Iris Kämpferi*. Neither

parent is in any way comparable for garden decoration with these Japanese Flag Irises, but the plant known as *I. levigata alba* and illustrated on page 144 is exceedingly beautiful. The so-called double varieties have regular six-petalled flowers, and the petals stand out almost horizontally. This characteristic they undoubtedly derive from *Iris setosa*. It is interesting to note that the Bearded Iris *Clematis*, which almost certainly represents a cross between a June-flowering Bearded Iris and a *Kämpferi* form, not only has six petals all in the horizontal plane, but that all the petals bear beards. The *Kämpferi* Flags have flowers in many shades of colour from

IRIS KÄMPFERI BY THE WATERSIDE.

white to deep purplish blue on the one hand and to more or less crimson on the other. The "self" self-coloured forms are preferable to the mottled ones, which in the garden give a rather "added effect." No list of names can be of much service to intending planters, for almost every nurseryman who specialises in these beautiful flowers has his own collection. In addition some of the sorts are listed by different firms under their Japanese names and English ones which may or may not be translations of the Japanese. Many thousands of roots of Kamperi Irises are destroyed each year because, under the impression that they are bog plants, the purchasers plant them in unsuitable places. These Irises assuredly like good soil and an abundance of water in summer-time, but they rapidly go back in shade and will not tolerate a sour, boggy soil. A fairly stiff loam or a rich marl mixed with an equal quantity of sweet-leaf-mould or spent hot-bed manure makes an ideal compost for all the species mentioned. The land should be deeply cultivated as well to provide drainage in winter as to ensure moisture in summer-time. For the Siberian Iris the land should not be over-rich, as this species seems to flower much better in soil of only average fertility.

There is one race of bulbous Irises which appreciates a cool, moist root-run. The English Iris (*I. xiphioides*) has a similar colour range to the Japanese Flags, and enjoys very similar conditions. It will, indeed, tolerate winter flooding and the consequent inevitable souring of the soil better than Iris Kamperi, and though it flowers best

in full sunlight, yet very strong colonies may often be seen in situations where they do not get the midday sun. The flowers of this species are large—almost as large as those of *I. Kamperi*—and the foliage and bulbs resemble those of the Spanish Iris, *I. xiphium*, but both are larger in all parts. As with Iris Kamperi, the self-coloured forms are best, but nowadays these are by no means easy to obtain. There was a time—not so long ago when new varieties were being steadily raised from seed, but presumably the raisers turned their attention to some other section possibly to quite another flower, so that to-day self-coloured varieties are almost unobtainable, which is a great pity. What became of the selfs raised twenty or twenty-five years ago? Well, the English Iris, like the *Freesia* and the *Tulip* and some other bulbous flowers, always "breaks" sooner or later into the blotched or mottled forms, which are never very effective and are often really ugly.

All the moisture-loving Irises are summer-flowering, most of them late summer-flowering, whereas the Bearded Irises flower in spring or early summer. There are numbers of water gardens planted now with Bearded Irises, but it is undoubtedly a mistake. Provided the land in which they are planted is sweet and not over-wet, they will grow and flower all right, but they always look out of place. There is an immense difference between the grassy green foliage of the moisture-loving Flags and the stout glaucous foliage of such Irises as *Fragaria* or *paludosa*. An equal difference is apparent between the grass-like

evergreen of the one section and the rigid-looking stalks of the other. Both sections may, however, be used in the herbaceous border, and since they do not flower together, they cannot quarrel.

To sum up, then, the Yellow Flag, Iris *Pseudacorus*, is the only species for shallow water; *I. silene* and orientals and their varieties will do in really wet ground, though such is not necessary; Iris *Moirieri* must have moisture and *I. aurea* and *ochroleuca* like moisture; Iris Kamperi never looks so well as by the water's edge, but, though it likes moisture, it will not grow in sour, boggy ground. Iris *xiphioides*—the so-called English Iris—likes similar conditions to the Kamperi forms.

The slender grace of many of these moisture-loving Irises makes them especially useful for gardens of limited area, for the small group gains in grace what it loses in massed effect. Iris *silene* is probably the most graceful of all, but one has only to see a solitary clump of some good Kamperi Iris to realise that the plant as growing has a grace which one would hardly expect from the cut flowers. For this reason it is very desirable when planting these Flags on a considerable scale to provide small outlying groups which will display the charm of the individual plant. It is well to plant all these Irises in drifts rather than in "blobby" patches approximating to the circular, nor should we let admiration for their soldier-like carriage tempt us to plant them to the exclusion of other moisture-loving plants of softer and more rounded habit.

IRIS KEMPERI, MORNING MIST, GLISHA AND STARRY HEAVENS.

ONE OF THE PARENTS OF THE KEMPERI IRISES—IRIS XIPHIOIDES ALBA.

SOME PLANTS OF A STREAMSIDE GARDEN

WHEN speaking of a stream garden some explanatory preface is essential, for the obvious reason that streams vary very much in size and character, and further, in the choice of one's plants one has to bear in mind that running water is a very different element to still water to deal with. In our particular instance the stream is not only a lively brooklet, apt to come down in spate after heavy rain and carry away with it anything which is less securely anchored than a Male Fern, but it is for the most part shaded by Alders. These latter are bad companions for most things, since their masses of surface roots often render soil preparation well nigh impossible.

However, in spite of the shade, the flooding and the Alder roots, we have managed to grow a number of plants along the waterside and this without any more interference with the natural beauty than has been found necessary. The most notable groupings, perhaps, are those of the herbaceous Spiræas. These are placed on the flattest levels which the rather too abrupt banks of the stream afford, and as far as the limited space will allow they are arranged in blocks according to size and colour, a "dotting" effect being avoided not less rigidly than overcrowding. Among the best of these are the well known Goat's Beard (*S. Aruncus*), the splendid *S. palmata* and *venusta* in various sizes and colours, *S. gigantea* and the dwarfed *Aruncus*, with the finely cut foliage, known as *S. Kneiffii*. *Astilbe Davidii*, very tall and rather too pucey in its fuzzy plumes, is here also, as well as the more graceful and pleasing *A. grandis* in ivory white.

A gentle slope which gets rather more sun than the above is occupied by *Omphalodes cappadocica*, now a mass of brilliant blue, which has become so happily established that it threatens to overwhelm *O. verna* and her comparatively heavy-eyed sister *nitida*, and even to oust *Tiarella cordifolia* from its fortress among the moss-clad rocks. *O. cappadocica*, however, is too beautiful for restraint.

Another early bird just here is the glorious little *Primula rosea*, which hangs on to life in a tangle of Alder roots and muddy sediment. *Mimulus lutea*, a rather dwarf mountain form, also enjoys the moisture, but not the shade, and I rather think its place would be better occupied by Globe Flowers, especially the very distinct *Trollius patulus*, which does not seem to be so plentiful as it was.

Azalea occidentalis grows among the Cappadocian *Omphalodes*. It is a late summer bloomer and a very fragrant, deciduous shrub, while on the opposite side of a short flight of steps leading to the water are some clumps of *Gentiana asclepiadea*. One of these, an extremely vigorous form, makes wonderful arching sprays up to more than 3 ft. in length, and two others of special merit are the very lovely pure white variety and the pale, luminous azure, Perry's Blue.

Close to the water, its yard-long arms resting on some floating grass, *Caltha polypetala* opens its broad leaves of shining, bronzy-green and fine butter-yellow flowers, and near-by are a double form of our own Marsh Marigold (*C. palustris*), the white-rayed *C. leptosepala*, and among them for later flowering lie the bulbs of *Sagittaria japonica*. This last, however, seems to need more sun than the *Calthas* and more than that fat and well-to-do *Arum*, *Lysichitum cantschaticense*, of which the ebony spike now showing at the water's brink will presently unfold and disclose the very splendid, glaucous-green leaves and equally splendid cowl of buttercup-yellow. This is a hardy, easy and noble Aroid, and one which deserves to be more widely grown.

There is now a stretch of the streamside mainly occupied by some of the lesser *Rhododendrons*, various members of the *Pieris* group, the excellent *Azalea ledifolia* alba, *Kalmias angustifolia* and *rubra*, a group of that fine old Lily, *L. tigrinum* var. *splendens*, with a rambling carpet of *Homocentron chionantha* (banished from more precious company) and winding up with some plants of the beautiful *Arundinaria auricoma*, hardy Ferns and a cheerful throng of self-sown *Borago laxiflora*. *Cardamine pratensis* fl. pl. and *C. trifolia* also appear here with clumps of *Anchusa myosotidiflora* and also the pretty *Ranunculus anemonoides*.

Rodgersia tabularis and *R. podophylla* occupy places on the opposite shore the round pea-green leaves of the one and the deeply cleft, bronzy red foliage of the other affording a good contrast. *Lythrum Salicaria* is also here, but does not thrive, since it craves for more sunlight. Our native Flag Iris does better. Planted almost in the shallow water and secured there until established, this hardy, handsome plant helps to collect sediment and prevent such things as *Calthas* and the dainty Water Forget-me-nots which grow among its roots from being swept away.

A little humpy promontory is taken up entirely by a cushion of *Polygonum vacinifolium* which has had a long fight for supremacy with *Saxifraga cuneifolia*, a delightful and diminutive woodlander which, having been defeated at the promontory, now leads its legions along the waterside path with the obvious intention of swarming over the rightful territory of a *toin*. *Homocallis*, which will probably take no heed of the invasion. Some of those tall old-time *Aquilegias*, with the broad, rather flat blossoms in creamy white and a good, clean blue, also adorn this part of the streamside and the adjacent path. There are many worse *Columbines* than these listed as novelties, the white ones being particularly fine and permanent. Another first-rate one for such a situation is *A. formosa*, lovely in foliage, elegant in form and bearing a long succession of scarlet and yellow flowers. This is a species from British Columbia.

Down nearer the water some shelving ledges have been made for the accommodation of the noble *Saxifraga peltata*, of which the tall, ruby-headed flower stems are already beginning to ascend. *Primula japonica* also flourishes here; there is a colony of *Trollius*, more Water Forget-me-nots and, of course more Ferns. As to these latter, Male Fern and Lady Fern predominate, and these grow so thickly that a judicious thinning out has to be effected at least once during summer.

There are a number of others, including *Osmunda*, *Onoclea sensibilis*, *Blechnum*, *Ceterach olivaceum*, *Scelopendrium* and various *Polypodies*.

Some of the shrubby *Spiræas* now come into view, *S. Bumalda* Anthony Waterer hanging its crimson

A STREAMSIDE GARDEN IN SUMMER.

discs over the water in early summer on one side and the taller, red-stemmed *S. Aitchisoni*, with fern-like foliage and glossy white flowers on the other. *S. Lindleyana*, not unlike the last in foliage, *SS. prunifolia* fl. pl., *confusa* and *opulifolia aurea* are also here, with a colony of the pink-plumed, trespassing *Douglasii* at a safe distance. All about these and among the Ferns there are Daffodils of various kinds, these doing better in the cooler soil of the water-side than anywhere else. There are hardy *Cyclamens*, too, and old-fashioned "Bunch" Primroses, "Butter Yellows" of the same household, one or two blue *Polyanthuses* and a few survivors of a once proud array of *Primulas Beesiana* and *Lissadel* hybrids which do not put up with such conditions here for more than a couple of seasons or so.

Orchis foliosa prospers exceedingly in a fairly moist, half-shady spot which it shares with *Vauconveria hexandra*, more *Cyclamens*, *Anemone Robinsoniana* and *Anthericum Liliago*. Beyond these there is a colony of *Galax aphylla*, whose polished green leaves, turning to crimson in autumn, would earn this plant a place did it never produce its tall and graceful tapered spikes of white. This cheerful thing now swarms over the graves of *Pyrolas* and *Shortias* and *Trilliums* which "died on us" years ago when zeal overran discretion in

matter of planting, and experience was being bought. *Cornus canadensis* is another little plant that loves the wild where autumn leaves are never gathered up, and in such places *Meconopsis cambrica* may be seen at its best without giving trouble. *Gaultheria*, *Shallon*, *prolumbens* and *trichophylla* are also in this company.

Nearest the water and where there is rather more light, the downy-leaved *Aster pyrenaicus*, with shaggy heads of cool lavender blue, makes a delightful

and upright sheaf some 3 ft. high. *Helleborus corsicus - lividus* is a striking object at all seasons, nor can the White Foxgloves be overlooked. These never look quite so handsome as when grouped, or even placed singly, among the native vegetation of cool situations in half-shade but with us they are by no means the easiest things to satisfy. Yet two other useful plants of stately character and for similar conditions are *Lysimachia clethroides* and *Solomon's Seal*. A. T. J.

ABOUT PRUNING ROSE TREES

PROBABLY undue importance is generally attached to the pruning of Rose trees. That is not to say that pruning is unimportant; every exhibitor knows that did he not prune he would never get a flower up to show standard. There are, however, many amateur gardeners who seem obsessed with the notion that they have only to prune the trees properly to obtain first-grade blossoms; they appear to think that pruning in some remarkable way provides the bushes with health and stamina. It cannot too plainly be emphasised, then, that pruning is only an incident of culture, that it will not

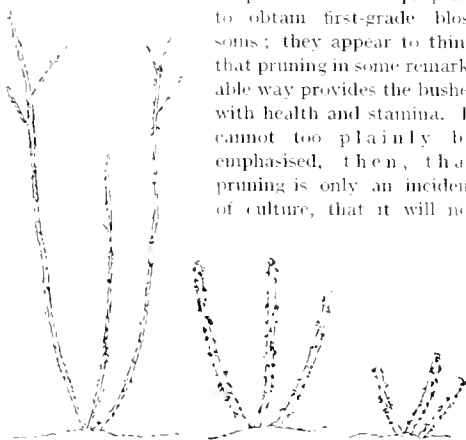

FIGURE 1. FIGURE 2. FIGURE 3.

in itself produce robust trees nor will its neglect necessarily bring the bushes to an untimely end.

If there is one section of the Rose to which pruning is more necessary than another, it is probably the multiflora hybrids (or Climbing Polyanthas as they are often called). Yet, give these varieties the conditions they love let them ramble "to their hearts' content" in the semi-wild shrubbery where their roots can be in shade—and they will go on indefinitely with very little pruning or none at all, getting bigger and more gorgeous year by year. This class of Rose should, properly speaking, be pruned immediately after flowering, but if this has been neglected until now it should be done forthwith. The pruning consists of cutting out all the oldest wood; indeed, for arch or pergola all two year wood should be cut away from vigorous trees, leaving only last year's strong growths from the base. In any event, at least one old shoot should be removed quite to the base to stimulate vigorous young growth from the ground line.

The average gardener, however, is now about to take in hand the pruning of his dwarf Roses. These are classed for the most part as Teas (T.), Hybrid Teas (H.T.), Hybrid Perpetuals (H.P.), Pernetiana (Pernet.) or Polyantha Pompons (Poly. Pom.) Actually, however, the placing of the varieties is somewhat arbitrary. Few of the newer Teas are "full-blooded," many of the H.T.'s have Pernetiana "blood," some of the H.P.'s are more than suspect, and even the Poly. Poms. shade almost imperceptibly but surely, year by year to the Hybrid Teas. Pruning by classes, then, is

likely to be satisfactory only to a limited extent. That is why the National Rose Society issues each year to its members a "Select List of Roses" with instructions for pruning. Readers of these notes who do not already belong to the Society are strongly advised to join, if only to secure this annual publication.

Those who already belong to the Society need not read what follows. They will find the directions given hereunder set out at much greater length in the little book referred to.

PRUNING AFTER PLANTING.

All Roses the first time after planting should be pruned hard; the only exception being those planted from pots, since they receive no damage to their root systems by the removal. Dwarf Roses should be cut down to within from 4 ins. to 6 ins. of the ground. Roses recently planted should have been pruned before planting, but if this was not done they should be severely pruned now.

SORTS WHICH REQUIRE LIGHT PRUNING.

All dead, frosted and unripe wood and all shoots which cross or approach too closely to a better growth should first be cut away. Many of the Roses which should have light pruning may be left as free bushes, in which case the thinning out already described is all the pruning they need. If, however, effect in beds is desired, some pruning (as distinct from thinning) should be practised. The long, strong shoots from the base may be reduced to a foot or so and the offshoots from the two year old wood may undergo a proportionate reduction in order to preserve the shape of the tree. The foregoing directions cover pruning for garden decoration. For exhibition

FIGURE 4.

purposes knife or secateurs must be used more drastically. More wood will be cut clean away and the remainder will be shortened by another third or even half its reduced length. Even so, as soon as the buds can clearly be seen (in May) it will be advisable to thin out a proportion of the young shoots to infuse more vigour into those left. Shoots bearing malformed buds will then be removed first, and afterwards the weakest of the clean buds remaining will be thinned out if necessary. Fig. 1 shows a strong young Rose bush. Fig. 2 shows the same bush pruned for garden purposes, and Fig. 3 for exhibition. A proportionate reduction will be necessary with Roses of less vigour, so that pruning for exhibition will not again be referred to. Hugh Dickson, Fran Karl Druschki, La France, Augustine Guinois-seau, Caroline Testout, Pharisier, Gustav Grunerwald, Lady Waterlow, La Fosca, Mme. Jean Dupuy, Maman Cochet and W. C. Clark are some of the varieties which should be pruned lightly. It will be seen that they are not confined to any one section.

The great bulk of the Roses belonging to the T., H.T., H.P. and Pernetiana sections commonly used for bedding purposes should be pruned moderately. For garden purposes from six to eight eyes should be left on the growth of the preceding year. It is understood, of course, that all dead, frosted, worn-out and crossing wood has been removed before the pruning proper takes place. A list of the varieties which should receive this treatment would be a very long one and a few typical varieties must act as pointers to the rest. That best of Teas, Lady Hillingdon, does best when pruned moderately, so do such H.T.'s as General McArthur, Lady Pirrie, Lady Roberts, Lady Ashtown, Mme. A. Chatenay, Joanna Bridge, K. or K., Liberty and Lient. Chauré and all the best of the Pernetiana sorts from the glorious Mrs. Wemyss Quin to the single Isobel. All but the strongest growing H.P.'s, too, will repay moderate pruning—such as General Jacqueminot, for instance—for the Hybrid Perpetuals as a class tolerate the knife better than do Roses with much Tea "blood."

Many of the Roses which require really hard pruning are naturally weakly growers, and the amateur will be well advised to cultivate as few of them as possible, for such have, generally speaking, little value for garden decoration. The shoots of the previous year's growth should, on such varieties, be reduced to from four to six eyes; indeed, with very weakly growers it is sometimes necessary to prune even closer. Very close pruning is essential if blooms of such varieties are wanted for exhibition. There are, however, some vigorous growers which are better pruned hard. Such are Lady Plymouth, H. V. Machin, Geo. C. Waud, Mrs. Henry Morse and Mrs. Geo. Norwood.

The Poly. Poms. are a class apart, though, as previously mentioned, novelties in this section, as far as growth is concerned, approximate more nearly year by year to the Hybrid Teas. The older varieties really need practically no pruning other than the removal of the old much-branched flower-stems and some of the oldest wood. They are very accommodating, however, and if a dwarf effect is desired, may be cut over quite close to the ground each season. Year by year the merits of this section for bedding purposes is becoming more fully realised. There is probably no hardy plant which will provide so much pure colour over so long a period as these dwarf Polyantha Roses.

China Roses resemble the Polyanthas in this, that they are very easily suited. They should not be pruned too early—it is better to see April in before a start is made, but, beyond this, they may have the dead wood removed and a little

thinning out done, or they may be cut back to near the base and, except that under the latter treatment they flower a little later, give equally good results either way. Noisette Roses which form laterals may be treated as if they were Teas. William Allen Richardson is the best known of this class. Those which, practically speaking, form no laterals, such as *Alister Stella Gray*, *Céline Forestier*, *Ophiré* and *Rêve d'Or*, should be pruned as little as possible. *Maréchal Niel* needs thinning severely, but the best wood of the preceding year should be left as long as possible. Prune the *Bourbon* and *Damask* varieties as if they were strong-growing Hybrid Perpetuals, that is, prune lightly or only thin out. *Provence* and *Moss* Roses should be pruned moderately. Climbing Roses of the Tea, H.T. and H.P. sections should on no account be hard pruned. So treated, they often become dwarfs and refuse to climb at all.

Whatever section the Rose belongs to, always prune to an eye pointing outwards, as in Fig. 4—where a newly made cut is seen at A. Start, if a knife is used, on the inside (*i.e.*, opposite the bud and cut slightly upwards. Do not start the cut below the bud or the latter will not draw the sap as it should do. On the other hand, do not cut midway between two eyes, so leaving an unsightly piece of dead wood. It is fashionable to decry the secateurs for any kind of pruning, but the fact is that, if kept sharp, they answer for Roses as well as the knife, and are more expeditious in use and involve much less risk of tearing the hands with thorns. The *Plucca* pruner, which holds the wood removed instead of dropping it, is exceedingly useful in some places, notably when pruning wall trees and there are brittle Lily stems or other vegetation below.

THREE CHOICE SAXIFRAGES

I THINK I am right in saying that those three rare Saxifrages, *Boydii*, *Faldonside* and *Cherry Trees*, were not only raised by the late Mr. Boyd of Melrose from the same parentage, but actually from the same seed capsule. Anyway, the reputed parentage of the three is *Saxifraga Burseriana* *S. aretioides*. Of

THE CHARMING LITTLE YELLOW SAXIFRAGA BOYDII.

the three, *Faldonside* is undoubtedly the best grower and the most beautiful. It has a neat, compact habit, with closely packed rosettes of narrow pointed leaves and 2 in. flower stems carrying one, two and sometimes even three flowers. These are very large and round and solid, of a glorious soft, clear yellow; the petals overlap one another to form an almost perfect circle and are ever so slightly crimped and crenated, which adds much to their beauty. Without a doubt, *Faldonside* is the most sumptuous and most beautiful yellow hybrid *Kabschia* Saxifrage in cultivation. This, in spite of the great number of hybrids that have been raised since *Faldonside's* introduction, and it must be an old plant as *Kabschia* hybrids go.

S. Boydii is a much rarer plant than *Faldonside*, partly because it is a less vigorous grower and partly, no doubt, because it is less beautiful and has therefore aroused less enthusiasm in the hearts

of propagators, but *Boydii* is, nevertheless, a very distinguished little plant, hard and very slow growing. Folk have given it a name for bad constitution. As a matter of fact, it merely resents bad cultivation more keenly than some of its relations. Mr. Mark Fenwick's wonderful pan specimens of *S. Boydii* at a recent R.H.S. show did not look very ill, or suggest bad constitution. The flower stems of *S. Boydii* are shorter than those of *Faldonside*, the flowers rather smaller, the petals do not overlap with the opulent splendour of *Faldonside*, and the colour is deeper, more of a citron yellow. No matter what hybrids are raised in the future, *Boydii* will always remain a most beautiful little plant, appealing to the true plant lover to exercise his skill in making it happy.

S. Cherry Trees is by far the rarest of the three—the true *Cherry Trees*, that is, for there are two forms in cultivation, and here let me make a confession. Many years ago I bought from the Craven Nursery a *S. Cherry Trees*. It came, a glossy, prosperous plant, strangely vigorous for so great a rarity, looking like a rather rollicking *S. Elizabethæ*. In all good faith I increased it greatly and distributed it widely. In those days I did not know that there were two plants—*Cherry Trees*, and the plant that goes under the name of *Cherry Trees*. I had got hold of the latter. I can only describe “the plant which goes under the name *Cherry Trees*” as being like a *S. Elizabethæ* which never flowers, and when it does forgives the dull! is “no damned good.” Soon after I began to distribute this ridiculous, false *Cherry Trees*, I saw the true *Cherry Trees*, and at once scrapped the false. That must have been ten or more years ago. Mr. Boyd himself shewed, at a flower show in the Caledonian Market at Edinburgh, a splendid specimen pair of *Cherry Trees*, a most distinct plant, practically *Boydii* over again, but with pale lemon-yellow instead of citron-coloured flowers. I have never seen the plant since until a fortnight ago. Then I saw that Mr. Stomouth offers the true *Cherry Trees* in his catalogue. I wrote for a plant at once and a sturdy specimen came, in flower, and sure enough it was the true *Cherry Trees* I had seen so long ago at Edinburgh. The description given by Farrer, in his “English Rock Garden,” refers obviously to the false, non-flowering *Elizabethæ*-like *Cherry Trees*, which goes

SAXIFRAGA BOYDII ALBA WHICH BEARS NO RELATIONSHIP TO *S. BOYDII* ILLUSTRATED ABOVE.

to show what a very rare and little known plant is the real, true Cherry Trees.

S. Boydii alba does not, except in name, come into this picture. It was raised by Mr. Boyd and

was named by him and has white flowers, but it is not a lot like Boydii, let alone a white variety of it. It is a larger, later thing altogether, much nearer S. marginata in general appearance, and,

consequently, S. marginata was one of its parents. It is, however, a handsome and desirable hybrid. All these Saxifragas enjoy well drained, sere soil or pot culture in the alpine house. C. ELLIOTT

THE QUEEN AMONG THE FLOWERS

IN spite of the dreary weather H.M. the Queen paid a visit to the R.H.S. Hall on March 17, primarily to see Sir George Holford's gold medal group of magnificent Clivias (Imantophyllum) and apparently found in the brightness of the many exhibits of spring flowers an

P. floribunda. A great many splendid plants were used, and it seemed that of all the varieties the dark blue King of the Blues was the general favourite. Then attention would pass to the still darker spires of

At the end of the hall Messrs. J. R. Pearson and sons set up a fine collection of Narcissi which they stated to be from "home-grown bulbs," and these

MESSRS. SUTTON'S REMARKABLE HYACINTH EXHIBIT.

SOME OF SIR GEORGE HOLFORD'S SPLENDID CLIVIAS.

inducement to make a long stay to only examine all the various collections.

Altogether there were three gold medal groups. Besides Sir George Holford's Clivias, Messrs. Sutton and Sons were awarded a gold medal for a wonderful display of Hyacinths, and Messrs. Sander and Co. won a similar honour with a superb collection of their famous Orchids, in which the new Cyndadumus, many gorgeous Cattleyas and fine plants of Dendrobium noble figured largely.

The Clivias were mostly grand plants of varieties named "We should not," and were the finest that have ever been seen at any show. They were grouped just inside the entrance, and the magnificent spires of gorgeous blooms made a memorable display. Grouped in front of these splendid plants were number of pots of Encheymas, and these, though perhaps somewhat overshadowed by the Clivias, displayed equally high cultivation.

Sutton's Hyacinths were arranged on a large blue space in an oval with blocks of colour radiating from a central grouping of Pyrus spectabilis and

Menech, and back to the paler blue Enchantress and on to the lavender Dr. Lieber, the red La Victoire and the white La Grandesse.

On the other side of the centre line of the hall Messrs. Carter and Co. had many good hyacinths attractively set within Maidenhair Ferns and with an imposing centre of King Alfred Daffodils. Among the Hyacinths the white Coraggio, the yellow City of Haarlem and the light blue Schotel were greatly admired, while the uncommonly coloured Orange Above attracted much attention.

Daffodils were also an important feature of the show, and Messrs. Barr and Sons had more of their wonderfully beautiful seedlings, particularly the large trumpets of rich yellow colouring. Among the named sorts of this type Silhouette, Vivian Gosnell, Gwendolyn, General French and King Harold were superb, while the vividly coloured coronas of Lady Bird, Lucifer and Sunrise compelled attention. Towards the centre of this large collection there was a good vase of Sea Nymph which has a long trumpet of pale shrimp pink colouring.

demonstrated that they are fully equal to the best from across the North Sea. A great many splendid varieties were represented, such as Phantasy, an almost white bicolor Trumpet; Brilliancy, a glorified Barrii Conspicuous; and Florence Pearson, a magnificent Trumpet which opens pure white and becomes creamy later. Mrs. R. Sydenham is also a splendid white Trumpet Daffodil, while Firebrand is a starry flower with a brilliant corona. The cyclamineus hybrid February Gold flowers, which were gathered from the open ground, were richly coloured and very charming.

The chaste Feels types were prominent in the collection of the Donard Nursery Company, who included Quicksilver, Southern Gem and a fine seedling. They also had good examples of other types, particularly of the large Trumpet sorts.

Drum Tulips, splendidly grown in bowls or fibre, were attractively set up by Messrs. R. H. Bath, Limited, and it only the day had been a little brighter they would have made a glorious show. At one end they had masses of the beautiful blue Glory of the Snow.

Rhododendrons were again a great attraction. The Falmouth collection included the rich pink Bernard Gill and Queen of Cornwall, besides many large trusses of *R. argenteum* and many barbatum hybrids. Messrs. Gill and Son also brought many spathes of *Arums* (*Richardia*) from out of doors. In Mr. Reuthe's exhibit there were trusses of several *R. barbatum* varieties, such as *Smithii* and *McLean*. Mr. Lionel de Rothschild sent a superb truss of *R. calophytum*, the white variety, which has a blotch of rosy carmine on the upper petal. It received an award of merit in 1920. He also showed *R. Lord Milner*, a bright crimson of large size. Mr. Michael L. Stevens had trusses of *R. Coverwood* and *Louise Stevens*, two deep crimson varieties.

Chief interest among lovers of flowering shrubs in general was focussed on the collection of *Wistarias*, *Laburnums*, *Pyruses* and *Brooms* which Messrs. R. Wallace and Co. arranged very attractively. The standards of *Cytisus Dallimorei* were very fascinating. They also showed the fragrant *Viburnum Carlesii*. Messrs. Cheal included a large bush of *Andromeda floribunda*. Messrs. Russell of Richmond staged forced *Clematises*. Miss Bateman and Sir Garnet Wolesley—with *Pyruses*, *Jasminum primulinum* and *Azaleas*.

The many flowers on the arch of Fortune's Yellow Rose made many wish this variety would flourish everywhere, and Mr. George Prince also showed long sprays of Yellow Banksian Rose and the new Allan Chandler, a fragrant crimson Rose. The comparatively new Coral Cluster was very beautiful as shown by Mr. E. J. Hicks, who also staged Premier, Columbia and Padre with other sorts. Coral Cluster is evidently

valuable for pot culture as well as for cut flower from under glass. Carnations were shown of the accustomed high quality.

Saxifrages were the most prominent of the alpinas. Mr. Clarence Elliott had the showy *S. Grisebachii* (Wisley Variety), *S. Sundermanni* (of Kew), a good tree-flowering white, was well shown by Messrs. R. Tucker and Son, who also had pretty pots of *Draba Dodeana*. The bright pink *S. oppositifolia* Wetterhorn was to be seen in several collections, and the rich blue *Pulmonarias* gave welcome colour. In Mr. Elliott's collection there was a well marked bush of *Thymus vulgaris argenteus*, which would be effective in the rock garden. Many plants of the greenhouse *Primula obconica* of a really good strain were shown by Messrs. Wm. Artindale and Son.

The only exhibit of vegetables was by Messrs. Sutton and Sons, and this was of high quality. Kales, especially the variegated-leaved sorts, were prominent and among the various Broccoli were Snow White and Eastside. The large roots of Radish Chinese Rose Colom attracted much attention.

NEW AND RARE PLANTS.

Clivia Field Marshal.—A stately spike of very large, perfectly formed, soft orange-scarlet flowers with pale yellow tubes. Award of merit to Sir George Holford, C.V.O.

C. Lady Holford.—This variety is of quite uncommon colouring, which may best be described as being pale apricot, which contrasts well with the clearly defined soft yellow tube. The spike was exceedingly large and the flowers were well

formed. Award of merit to Sir George Holford, C.V.O.

C. Westonbirt Perfection. In size of spike and in the perfection of the large round blooms this variety ranks among the very best in cultivation, and added to this is its vivid, glowing orange-scarlet colour that contains a suggestion of rose-pink which harmonises perfectly with the soft yellow of the tube. Award of merit to Sir George Holford, C.V.O.

Narcissus Golden Empress. This is a rich golden form of the well known bicolor Trumpet Daffodil. The flowers are just as large and well formed as those of Empress, and the award was given as a show variety. Award of merit to Messrs. Barr and Sons.

N. Great Dane. This is also a show variety and is a large, rich yellow Trumpet Daffodil with a slightly paler perianth. It has a widely expanded trumpet, and the vase of blooms was distinctly decorative. The variety will be best visualised if we think of it as a giant Emperor. Award of merit to Messrs. Barr and Sons.

Pernettya mucronata Bell's Seedling. Several sturdy bushes of this useful berried shrub were shown, and these carried large quantities of crimson berries, making it a useful plant for the front of the shrubbery. This is a very good type of *Pernettya*, but hardly distinct enough to be worthy of an award. Shown by the Donard Nursery Company.

Saxifraga Valerie Keevil. This is a very beautiful addition to coloured Saxifrages. The plant makes a neat little cushion of silvery leaves from which spring large flowers of deep carmine colour which merges into a bright purplish maroon

LIKE A GIANT EMPEROR, NARCISSUS GREAT DANE.

THE RICH GOLDEN YELLOW NARCISSUS GOLDEN EMPRESS

in the centre of the flower. The colouring and size of the flowers make one think of *Saxifraga oppositifolia*; this is a real advance. Award of merit to Mr. M. Prichard.

Stachyrys chinensis. This is practically a Chinese form of the Japanese species *S. praecox*, which is only moderately common. The slender pendulous racemes of pale yellow flowers are somewhat stiffly set at an acute angle on the stentish, leafless branches, and they were more freely produced than is the case with *S. praecox*. Although the flowers have no individual beauty, the generous vase of sprays was quite attractive, and would be an admirable associate for sprays of *Cydonia* (*Pyrus*) japonica, and its flowers are welcome at this season in the shrubbery. It is generally hardy on fairly light soil. Shewn by the Director, Royal Gardens, Kew.

Cymbidium insigne rhodochilum. The plant bore two long, arched spikes of flowers of the same colouring as those of *C. St. Andre*, but much smaller and not so well formed. It was, however, a graceful

flower of considerable attraction. Award of merit to Messrs. Sander and Co.

C. St. Andre. A tall, erect spike of large rounded blooms. The perianth segments are ivory white and, in direct contrast, the lip is spotted and flushed with rose purple. An uncommon and attractive Orchid. Award of merit to Messrs. Sander and Co.

C. Merlin, Westonbirt Var. The rounded, substantial flowers have milk-white petals which are flushed and lined with old rose pink and have a golden crest. First-class certificate to Sir George Holford, C.V.O.

Odontioda Dora.—A dainty Orchid of uncommon lilac colouring. There is a distinct white margin to the lip. Award of merit to Messrs. Charlesworth and Co.

Odontoglossum Llewellyn. The spike bore two large, perfectly formed blooms of dull chocolate lightly margined with a paler shade of the same colour. The lateral sepals were attractively serrated and the large lip was waved. First-class certificate to Mr. H. E. Pitt.

plants that demand less skill or respond more readily to simple care and what may be termed liberal treatment.

The present-day strains make rhizomatous stems that ramble over the ground, rooting as they go and producing a succession of flowering growths throughout the season. Moreover, they survive an ordinary winter and break into new growth in spring, forming, the second year, a dense carpet of verdant foliage and glorious blossom. The principal cultural demand of *Mimulus* is unstinted supplies of water, and with this requirement satisfied throughout the growing season, the plants will grow in all sorts of soil and in either full sun, or partial or entire shade.

To establish a bed the most satisfactory plan is to plant out of pots about the latter end of April or early in May. A fair amount of well rotted manure may be buried under the plants, and occasionally during the flowering season a soaking of liquid manure may be given. Cut back old stems at intervals to encourage and strengthen young growths. A. J. MACSLE.

THE FLORISTS' MIMULUS

Modern Development of an Old-fashioned Favourite Flower.

THOSE of us who can look back over a good many years of horticultural activity, and who can, moreover, recall the gardens of our grandparents—when those gardens were to us, in those buoyant days of childhood, just glorious places in which we could waste away sunny hours and seek the ruddiest Strawberry and the most juicy Plum—will remember that among grandma's most cherished flowers was the gaily spotted *Mimulus*, which the dear old soul, having no liking for botanical names, persisted in calling her "Monkey Musk." Tall and soft in growth, the Monkey Musk was supported on a dainty made "ladder" of thin strips of wood, and the plants grew and bloomed profusely, although, admittedly, the individual flowers were scarcely the size of a Foxglove.

For some reason the *Mimulus* was numbered with other old-fashioned flowers that seem to have lost their hold on the affections of gardeners, both professional and amateur, and of more recent years one might pass through many villages without catching sight of a single Monkey Musk in the cottage windows.

I have heard it declared that no really well loved flower ever dies out, but, even though Dame Fashion, idle with her favours, may for a while turn her back upon this flower or that, the good things are sure to capture the affections of some alert enthusiast and retrace their steps to the ranks of popular favourites.

The *Mimulus* is, I venture to opine, about to enjoy such a restoration to the public favour, but the modern *Mimulus*, which is already attracting much attention, is a very different flower from the Monkey Musk of our grandmothers' gardens and window ledges. Dwarf, sturdy growth, large deeply veined foliage and great trumpet flowers with wide throats and broad margins take the place of the tall, elongated branches with small flowers at intervals. In colours, too, great improvement has been effected. The prevailing colour of the throat is a rich golden yellow or glowing orange, over which the velvety crimson or bright vermilion bands, blotches and spots shew to infinitely greater advantage than in the old types wherein white throats, plum-coloured blotches or pale yellows and brown spots prevailed.

The modern *Mimulus* is indeed a flower of size, symmetry and gorgeous colouring that cannot

fail to arrest attention. During the summer of 1922 thousands of people were attracted to the flower by beds planted with a particularly fine strain called Chalk Hill Giant in Regent's Park and also in the Royal Botanic Gardens. This year arrangements have been made for a greater display in both these places, and also in the gardens at Buckingham Palace, St. James's Palace and Kensington Gardens. Thus the popularity of the modern *Mimulus* is assured, for there is no surer way of courting fashion's favour in flowers than to give a particular plant prominence in the leading parks of London.

It is essential that any flower that aspires to widespread popularity shall be easily grown to perfection by the average garden owner, and in this respect we surely have no ground for fears in regard to the *Mimulus*, for few indeed are the

A LITTLE WOOD LILY

The Wood Lily illustrated below, *Trillium nivale*, is one of the easiest of the genus to grow and very charming, but it is by no means common in gardens. Like all the members of this family, it likes a deep moist soil, rich in humus, with some shade from the midday sun. It is wise to plant it rather deeply. The general colour of the blossoms is the white, and the spots shewn in the illustration are purple. Though almost as dwarf, this species must not be confused with the tiny snow white *T. nivale*. There are in many gardens spots which seem almost to shout to be planted with Wood Lilies and which only require a little trouble in making up a suitable compost to provide a beautiful spring-time picture. These plants are by no means difficult to grow; indeed, given the proper compost to start with in a place where they will never suffer from drought, they will quite well take care of themselves.

TRILLIUM NIVALE.

CORRESPONDENCE

LILIUM REGALE.

IN one respect I submit that scant justice is done to this Lily in "G. D.'s" notes on page 118. He says that "it rarely produces more than four flowers on each stem." That is contrary to our experience here, where I have counted seventeen blooms on a single 5 ft. stem and fifteen on another of equal height, neither stem being fasciated. It is true that so great an effort exhausts the bulb for a time, reducing the number of flowers in the following two or three years to five or six. Being somewhat prejudiced against florist's hybrids, and, greatly preferring the natural species, I shall not be accounted an impartial critic in saying that no sulphur-gale Lily that I have seen is equal in beauty to either of its parents. Those which I have received and grown have proved far inferior to both. The specimen described by "G. D." as a "much improved and larger regale" must be a truly fine thing, though, personally, I am unable to visualise improvement in *L. regale*. It may be useful to note that, whereas *L. regale* is a lime-lover, its near relation, *L. Sargentiae*, detests lime.—HERBERT MAXWELL, *Monreith*.

PRUNUS BLIREIANA.

WHAT a delightful shrub this is! So superior is it to its parent or congener, *Prunus Pissardi*, that one is at a loss to know how it originated. In the South, *Prunus Mume* in its best forms is still brighter in colour, but it is not so hardy, and as it is still earlier in its season of flower, *Prunus Blireiana* is the better plant for northern gardens, and its large and prettily coloured flowers rival the Cherries of later spring. As a bush it is less exposed to bad weather than when grown as a standard, and deserves the privilege of a sheltered nook where its blossoms may expand, followed as they are speedily by the brown foliage that dies off in autumn in a glow of brilliant colouring. It has the most perfect effect when grouped with *Megasea ligulata*, which flowers at the same time and enjoys the same conditions. No garden should be without these two early-flowering beauties.—E. H. W.

[Both *Prunus Pissardi* and *P. Blireiana* are, botanically, varieties of *Prunus cerasifera*. Actually, one imagines PP. *Blireiana*, *Moseri*, *nigra*, etc., are garden varieties obtained from *P. c. Pissardi*.—ED.]

FRAGRANT FOLIAGE.

I REMEMBER the old-fashioned plants of country gardens, grown for their scent, and mentioned by W. Linders-Lea on page 124, and can add a few more. At the time I write of, there were no more universally cultivated plants in country gardens than Costmary or Alecost (*Balsamita vulgaris*), variegated Balm (*Mentha rotundifolia variegata*), golden variegated Balm (*Melissa officinalis aurea*), common Thyme, Lemon Thyme, Southernwood or Old Man, and Bergamot Mint (*Mentha citrata*). Indeed, I was a cultivator of the above and left the cutting to the women-folk of the household. I still have the first and last of this list, as well as two of the others. The Costmary, *Mentha rotundifolia variegata*, and others were cultivated by John Gerard in his garden at Holborn in 1597, and I guess they have been in the country ever since. To discard them would be unthinkable. Foliage is still wanted for mixing with flowers to tone down their brilliant hues, to add lightness to arrangements, and scent. To the above ought to be added the old, crimson Damask Rose and the fragrant, white *Rosa alba*. Peppermint, Wormwood and Feverfew were grown for making tonic drinks by some of the

oldest inhabitants. *Pelargonium graveolens* was the first scented Geranium I met with, and later found the Peppermint Geranium. A nursery firm's catalogue of this year contains sixteen species and hybrids, including Pretty Polly, and a number of them can be seen in the windows of some Surrey

A FINE WHITE SEEDLING DELPHINIUM.

towns and villages. The most delicately coloured of the silver tricolor Zonals I can remember was Italia Unita.—J. F.

A BEAUTIFUL CODONOPSIS.

AS a Bellflower, *Codonopsis ovata* is certainly distinct and beautiful, as stated by "S. S.," Warwickshire, page 124. In my opinion the interior of the flower is more beautiful than the exterior, but this cannot well be seen without lifting up the flower. One way of growing it is to plant it on the top of a bank of the rockery or even the top of a retaining wall. The dwarfier species lie down on the soil, but some of the taller

ones are twining herbs. I have seen *C. ovata* climbing a little on sticks and on a high bank where one could see into some of the flowers. One reason for the unpopularity of the class is the rather rank smell of the herbage when handled or bruised. I was recently shown a new one introduced from China, and although it had not then flowered the gardener was offended by the smell of the leaves. In a small way this can be detected by bruising the leaves of almost any Bellflower, but in *Codonopsis* it is greatly intensified—in some species more than others. The smell of Garlic, however, in *Allium neapolitanum* did not prevent it becoming popular as a cut flower some years ago.—H.

A WHITE DELPHINIUM.

I AM sending you a photograph of a white Delphinium raised from seed sown in September, 1921. The plant flowered in June of the following year. It was one of a batch of seedlings, the seed of which was saved from the variety known as Commandant Chapuis. Seed from this particular variety, I find, gives excellent results, most of the seedlings being of exceptional merit.—W. C. BLAKEWAY, *Hampton Lovell, Droilwich*.

AN OLD FAVOURITE.

THE beauty of *Chrysanthemum Source d'Or* is all that "Claremont" says of it on page 125. There are two sports from it, namely, Lizzie Adcock (deep yellow) and *Crimson Source d'Or*. Sorcerer has similar but larger flowers. All add to the reputation of the original. *Source d'Or* begins flowering in many gardens in October, and if the weather is favourable it looks very handsome. I saw it flowering in gardens at Skegness, Lincolnshire, at the end of last December, so it has a fair reputation for being hardy. In its own colour it has not been superseded. There are some older varieties in cultivation, however, and listed in some of the leading catalogues. Mrs. G. Rundle (pure white), Mr. G. Glenney (a primrose sport from it) and Mrs. Dixon (a bright yellow sport from the latter) are three small incurved varieties that were grown for cut flowers in the seventies of last century.—HORTULANUS.

A DWARF CINQUEFOIL.

POTENTILLA TONGUEI appears to be one of the survivors of a large and interesting class of hybrids raised in the forties of last century, most of which, unfortunately, have been lost. I believe that I am correct in including it among these. It has held its own well by reason of its distinctness and value for the rock garden. I have been acquainted with it for forty years or so, when I first came across it in the collection of a keen alpine grower, long since departed, whose treasures comprised the best and choicest of rock plants to be procured at that time. *P. Tonguei* was a cherished plant of his and he guarded zealously the secret of where it could be procured. This is not a spirit to be commended, of course, and those of us who desired also to possess *P. Tonguei* were not long in discovering where it could be purchased. It is a low grower, rather trailing, with typical Cinquefoil leaves and good single flowers of a fine orange yellow with crimson spots. Its height is about 4 ins. in an ordinary rock garden compost of loam, leaf-soil and sand. It grows quite well in sun or shade and is propagated by division or by cuttings. It has been well called by one of our ablest and most impartial critics a "treasure of the garden." Such it is, and it deserves to increase in favour among those who seek good reliable plants of real beauty.—S. ARNOTT.

A BRILLIANT TRAILER.

DURING the hot, dry summer of 1921 *Verbena chamaedrifolia* was one of the finest sights on the rock garden, and another spot where it was quite at home was on a narrow border facing south at the base of a dwelling-house. Last year it was not so fine, but still there were enough flowers to make it attractive. It has a creeping habit and the large, showy flowers are a brilliant scarlet which in a mass are most effective. In Gloucestershire it will live in the open throughout the year, but no doubt a severe winter would kill it. Nevertheless, it is worth a little trouble, and the stock could be kept up if a few specimens were potted up and placed in a cool greenhouse. Ample cuttings would be available in the early spring. *V. chamaedrifolia* should be given a sunny position on the rock garden where it is not too wet, in a rooting medium of loam and leaf-mould. It is of Brazilian origin, and was introduced into Britain in 1827. As a pot plant for the cool greenhouse this *Verbena* can be recommended. I have grown it as a trailing plant, and with the growths neatly staked in an upright position. Both ways were successful; but, indoors, white and green fly are troublesome and must be held in check by fumigation or spraying, otherwise the plants will soon become unsightly.—B.

FOR DRAPING STONES.

IN some rock gardens there will be found a number of large boulders which need draping with plants, and if such boulders are numerous it is difficult to do this without a good deal of repetition. One does not like to employ *Arabis* and *Ambrieta* too freely, and as a change I would suggest *Verbena radicans*.

Here, in the Chepstow district, it grows freely, the procumbent stems making considerable growth in one season, while the fragrant lilac flowers are fairly numerous during the summer months. The foliage is pleasing at all times, and it will cover a large stone in a couple of seasons. It will succeed in almost any position (dense shade excepted) and is, moreover, not particular as to soil.

The stems form roots at intervals, so the plant can readily be increased. It will also root freely from cuttings in August if placed in sandy soil in a cold frame. Whether *V. radicans* would be hardy in all districts I cannot say. According to Nicholson, it came from the Andes in 1832, and it is referred to as a greenhouse sub-shrub. In any case it would be advisable to keep a few plants in a cool greenhouse during the winter months to replace any that were killed by hard frosts.—T. W. B.

ON THE NAMING OF NOVELTIES

IN these days when so many garden lovers, both amateur and professional, are engaging in the fascinating pastime or business, as the case may be, of raising novelties, a few notes on the naming of such seedlings may be of interest. This subject was mentioned very briefly by Rev. J. Jacob in writing on Dutch Irises (*THE GARDEN*, September 9, 1922, page 451), and I am certainly in agreement with his sentiments as there expressed.

I have often wondered that so many of the most prominent of present day raisers have exhibited so very little ingenuity in naming many of their novelties. In the following notes I propose to express some of my own opinions on the subject, and briefly to discuss the naming of such well known and popular plants as the Rose, Daffodil, Gladiolus and Bearded Iris.

It may be asked, What are the essential points in naming a seedling well? I reply that the name should be (1) distinctive, (2) euphonious, (3) short and (4) in some cases it may well be descriptive or partly so. To elaborate slightly on these points. The reason for (1) is obvious, to avoid the confusion of using names too much alike, which ought not to be tolerated under any conditions. As to (2) it is equally obvious that many flowers have ugly-sounding names, which might easily have been avoided by the raisers. In the case of (3) perhaps I should have said "not long" instead of "short," by which I mean that names should, for the sake of brevity and convenience, never consist of more than two words or (say) five syllables in all. Or (4), when it is intended that the name be descriptive of the flower, care should be taken that such description is correct and accurate; any tendency to exaggeration or misdescription should be studiously avoided. Plenty of examples of badly named plants under points (1), (2) and (4) will at once occur to most readers, while as sinning most thoroughly against (3) need I quote more atrocious examples than the Roses Suzanne Marie Rodocanachi and Marie Adelaide Grand Duchesse of Luxembourg?

The habit of naming novelties after the friends or acquaintances of the raiser has, I think, been carried much too far, and, while it may be very nice and flattering to the persons immediately

concerned, is apt to be most tiresome and annoying to the general horticultural public, especially when a batch of initials is added to the name. It will be universally agreed that it is altogether too bad to find some lovely flower blessed ("cursed," did I hear someone murmur?), with such an *equivocal* name as, say, Mrs. N. Q. de Jones-Smyth, which, though not an actual name, is an example of a type which is only too frequently met with. In one catalogue I have before me, names beginning with "Mrs." occupy nearly six pages! See also *THE GARDEN* for 1922, pages 505-6 and 546-7, where the great majority of names fall under this head. I do not wish readers to think that I am condemning this method of naming altogether, I say, however, that it is done much too frequently, probably because raisers are too lazy to think out a better name! And I will say that I commend the naming of some flowers after well known horticulturists and raisers, for what monument could better perpetuate the memory of those who have worked untiringly and well for the improvement of one or more species of plants!

Again, novelties should not be too often named by a colour in conjunction with some other word; it tends to monotony and is also inclined to be misleading. Look at any copy of the classified list of Daffodil names of the R.H.S. here I find in one (of not very recent date, too), that fifty-two names begin with the word "red," and no fewer than eighty-four with "gold" or "golden"! And not infrequently the implied description contained in the adjective is none too accurate.

As to names intended to be partly or wholly descriptive of a flower or of a prominent feature of it, many mistakes and misrepresentations can be found: for instance, flowers are called "star" or "starry," when not even remotely so in any way; or, perhaps "butterfly" (which implies lightness and daintiness) is given to a very solid looking flower, or even in some cases "dream," where it might more correctly have been called a nightmare! It might be as well to add here that such ludicrous names as Incontenable, Unsurpassable, etc., may well be avoided for untruth.

To specialise a little, the Rose, queen of the garden, has suffered much in the naming, probably

more than most flowers, and I think that a glance at any catalogue will show that at least 75 per cent. have been named after persons either real or fictitious; this aspect I have already dealt with. Of the remaining 25 per cent. it is a great pity that such excellent and commendable names as Brilliant, Cheerful, Modesty, Prince Charming and Sunburst are not much more numerous than they are. No one will deny that names such as these are infinitely more suitable and decidedly preferable to the type above mentioned.

Mistress Daffodil has fared better, though the naming by colours already referred to has been carried too far, otherwise the Daffodil has been named rather well. For instance, what could be better or more suitable than such names as Alpine Snow, Angel's Tears, Circlet, Icicle and Phantasy, to quote a very few. But here are some mistakes, or, if you will, errors in good taste, in naming. Lord Kitchener, which should be a big, coloured flower worthily to represent that famous soldier, we have as a rather small flower in white and lemon, most unsuitable; while Mrs. H. J. Veitch, in defiance of the fact that grace and daintiness are attributes of the fair sex, is a deep yellow flower, bold and very massive, a comparison which seems scarcely complimentary to the lady after whom it was named. Again, to quote an error in a descriptive name, one example will suffice, others are not infrequent; that lovely flower Lemon Star cannot by the wildest exaggeration be called a "starry" flower and there is very little lemon in it at all, it is more a creamy primrose which fades to almost white.

The Gladiolus is, on the whole, well named, though several colour names are very misleading, and why, oh why! must catalogues continue to describe as "blue," colours which are indisputably shades of purple? Lavender, lilac and slaty purple shades there certainly are, but true blue, either light or dark, I have yet to see in any Gladiolus. As this is at present, at any rate in this locality, the flower which is booming above all others, it is to be hoped that raisers will exercise discretion in naming and keep the type of name at least up to the present standard.

The Bearded Iris is, I think, certainly the most happily named of the four flowers I have specially mentioned. To quote just a few examples of excellent naming, Afterglow, Caprice, Dimity, Storm Cloud, Quaker Lady and Sunshine. Here, also, too much care in differentiating between shades of blue, purple and near pink cannot possibly be exercised, as it is often difficult to decide what some of the wonderfully delicate shades of colour really are.

Perhaps after this someone will say, "But all the best names are already taken—what are we to do?" And this, I grant, will appear to be rather true, for instance, after a perusal of the R.H.S. list of classified Daffodil names. Please note I only say "appear" to be true; for, in reality, there are plenty (and I emphasise that word!), plenty of excellent names as yet unappropriated, if only one will think and look round for them, and I simply refuse to believe that many present day raisers are as lacking in ingenuity and originality as some naming would imply. Therefore, you raisers of novelties, for the sake of the beautiful flowers which your enthusiasm and enterprise has called into being, and for the sake of the horticultural public which grows them and loves them, think well before you decide, give your imagination free play and with them let originality and good taste combine to give a name which will be worthy of the flower on which it is bestowed and which will go on, not as an evil necessity to be only tolerated, but as a happy designation to be loved and remembered through the years.—"AUSTRAL," Geelong, Australia.

THE ANT IN THE GARDEN

How to Make the "Eggs" of Use.

PROBABLY most alpine gardeners have at times been troubled with ants in the rock garden, and I find, in my own case, that very frequently these little creatures select one of my choicest plants under which to make their nest. As this process necessitates considerable tunnelling operations below the ground level and the bringing to the surface grain by grain of large quantities of soil, often completely burying some choice alpine plant under a conical hillock of fine granular particles, it will be readily understood how serious the effect may be. Not only is the foliage end of the plant (often of a woolly character) submerged and excluded from the light, but its root-run is so honeycombed with tunnels that its attachment to the soil is grievously loosened and the moisture so rapidly drained away that if attention is not speedily given to it the plant must succumb.

I have yet to find a really satisfactory method of dealing with this nuisance. I have tried constantly soaking the affected area with water, but the ants seem so efficiently to have drained the subsoil that before the nest is really drenched the plant has suffered considerably from prolonged wetness on its foliage. Another method sometimes adopted is carefully to make a hole in the immediate vicinity with a stick or piece of gas piping and pour into it a solution of cyanide of potassium, afterwards plugging the hole with a piece of moss. Ants are peculiarly susceptible to the gas given off by this chemical, but owing to its extremely poisonous character to human beings it is rather dangerous stuff to have about in the vicinity of one's garden.

The two illustrations given herewith depict, not a method of curing the evil, but a simple arrangement whereby we can at least turn it to some good account. The only really satisfactory method I have yet found of dislodging the ants is to unbuild that portion of the rock garden

affected (usually quite a small area) and after carefully taking out the plant, which may with advantage be potted up and nursed awhile until

resulting from digging out the nest. On the other hand, to throw on to my pool whereon are floating brilliantly coloured *Nymphaea* flowers, the contents of the bucket would mar its beauty for many days owing to the mud which would stain the water and the general detritus which would float on its surface. The alternative, of course, is to separate the eggs from the rest of the mixture -

AN ANTS' NEST AS DUG OUT.

it recovers its health, proceed to dig out the nest. Like so many rock gardeners, I have in association with my alpiners a small pool or two wherein fish make their home. Knowing how they relish fresh ants' eggs (really the larvae of the ant and not eggs at all), it has always grieved me to throw away the bucketful or so of ants' eggs and soil

a tiresome task indeed in view of their number and the very lively character of the angry ants incorporated therein.

The accompanying illustrations shew how this separation may be done promptly and efficiently without the expenditure of more than a few moments of time. The method I adopt is as follows: The contents of the bucket containing the ants, ants' eggs and soil is, directly after digging out, spread in a thin layer, covering perhaps 2ft. in diameter, upon a hard gravel path or pavement, and near to this heap is placed a piece of thick brown paper, the corner of which is allowed slightly to overlap the edge of the patch of mixture. One or two stones are then placed on the paper to prevent it blowing away. The whole is then left for an hour or two, when if the stones are removed and the paper lifted up it will be found that practically the whole of the eggs have been carefully removed by the diligent ants and placed in a neat, compact heap beneath the shade of the paper in a suitable condition easily to be scooped up and placed in the pool without in any way damaging its appearance, and to the great delight of its "finny" inhabitants.

The simple explanation of this, at first sight, extraordinary phenomenon is, of course, the fact that the ants seek to hide away their larvae from the light. We afford them the necessary shadowy spot in close proximity to the heap and they readily take advantage of it as the handiest place of retreat.

SHRUBS FOR BLEAK GARDENS

MY notes on page 60, February 3, might be supplemented by a reference to the genus *Philadelphus*, which yields valuable species and varieties for the embellishment of town gardens. The roughly hemispherical habit of the shrubs is pleasing to the eye, and a maximum height of 12 ft. makes them suitable for cultivation in small gardens. I have proved that the Mock Oranges, as the members of this genus are commonly called, require a sunny aspect to develop their ornamental qualities to the full. Thoroughly ripened wood is a necessity for the production of bowers of bloom, and only sunshine can achieve this. It is often stated that Mock Oranges will thrive in shaded situations. I agree, it wealth of growth may be set up as the standard of excellence. They will spread themselves in the shade like the proverbial green Bay tree, but flowers will be conspicuous by their absence. A moderately rich soil is necessary to sustain a healthy and evenly vigorous growth. It is well to trench the

spot at the base of each petal. The other Mock Oranges enumerated above are pure white in colour, and all of them bloom towards the end of June. The *Diervillas* (also called Bush Honeysuckles) bloom about the same time, and they are of real value to northern gardeners, particularly those who labour under the disadvantages of an industrial area. There is no vital difference between the cultivation of Mock Oranges and the *Diervillas*. In my judgment the latter exhibit a greater tolerance for partial shade. My own garden contains specimens from which the brightest rays of the sun are screened, and they afford every satisfaction. I have arrived at the conclusion that a moderate amount of light is sufficient to mature the wood. The species *rosea* is worthy of a place in every collection because of its reliability. I can confidently recommend the cammie variety *Abel Carrière* to all lovers of the *Diervilla*; *Coquette* also merits praise. This variety is said to be the largest-flowered *Diervilla* in cultivation. With me the individual rose

feature of the garden. Sometimes accommodation can be spared at the apex of a retaining wall or on a rockery. It is easily suited from a cultural standpoint. Soil of light or medium texture is best, and it is absolutely essential that the drainage be above suspicion, for the species will rapidly languish in stagnant soil. No pruning is required other than the removal of dead or unhealthy shoots. If the *Olearia* can be planted in proximity to the purple-leaved *Prunus* *Pissardi*, a beautiful colour effect will be established.

GEO. H. COPLEY.

ABOUT POTATOES

POTATOES! I hear someone say. "Why, anybody can grow Potatoes; why waste valuable space about such common things?" Perhaps it is true that anybody can grow them, but when we learn that the average yield in this country is only 6 tons to the acre, it shows there is something wrong, and those who can do so should endeavour to mend matters in this direction, for the crop is more important than Grapes or Daffodils.

Although it is being continually drilled into them, cultivators seem frequently to forget that perfect edible roots, perfect fruits and perfect seeds can only be produced by perfect leaves, and that perfect leaves are impossible without direct sunlight. Dr. Masters says in *Plant Life*:—"Arrived at the seed, the glucose is turned back into insoluble starch, to be reserved for use when required. The process is essentially the same in the case of the tuber of the Potato, the 'bulb' of the Turnip, or the root of the Mangel. All these organs are severally storehouses wherein food is accumulated for future use. The food is neither made nor elaborated in them, but simply stored, having been formed in the leaves and conveyed to the storehouses."

Well, then, take the case of the Potatoes. We will suppose that every care has been taken of the sets. They were placed in single layers, with the best eyes uppermost, kept in a comparatively light shed and protected from frost till planting time. All this is perfectly correct, but what follows is frequently not such good treatment. They are often planted in rows not more than 2 ft. apart and frequently less.

I do not know whether it is a general practice, but in this neighbourhood, as soon as they are a few inches in height they are what is locally called "hacked," i.e., the soil is loosened with a hoe or a "turn pick," which is a digging fork bent into the form of a hoe. This is done to a considerable depth and close up to the stems of the tubers. Earthing up follows in a few days time.

Now I have found the roots start spreading at a very early stage, and the "hacking" breaks many of them off and exposes others. If it must be done (and in heavy soils there is an excuse for it if there has been much trampling), it should be done as soon after planting as possible, and earthing up finished before there is any danger of injury to the roots. Where, however, the soil is really heavy, or not so dry as one would like it, I prefer at planting time to fork over the ground just sufficiently wide for one row at a time and not tread on the dug ground at all.

I have proved that 2 ft. between the rows is not sufficient, excepting for early, short-hauled varieties, and that heavier crops can be produced by more space. It should be remembered that most plants, including Potatoes, take in more food, with the exception of water, though their leaves than by their roots, and for actual feeding purposes this is principally, if not entirely, confined to one

THE LATE-FLOWERING PHILADELPHUS GRANDIFLORUS (SCENTLESS).

site at planting-time and to incorporate 5 cwt. of dung with each 20 square yards of ground.

Pruning is an important item in the culture of the Mock Orange, and yet how rarely is this realised. It is a common sight in suburban gardens and in public parks to see the shrubs "clipped into shape" with a pair of hedge shears. What a tremendous error! Such treatment greatly reduces or entirely wipes out the following year's prospect of bloom. Mock Oranges bear flowers on one year old growth, which should be allowed to remain and be afforded every opportunity to ripen. It is sound practice, therefore, to prune immediately the flowers have fallen, removing growths which have flowered or are too weak to do so. I have cultivated the species *P. coronarius* and *grandiflorus*. Both of them flower in June and are very useful, the flowers of *grandiflorus* being particularly large. Lately, however, I have centred my affections upon certain Mock Oranges of hybrid origin. One of these is *Avalanche*, a perfect gem, bearing large and fragrant flowers. *Gerbe de Neige* is exceedingly floriferous and a very certain "doer." The charm of *purpureo maculatus* impresses itself at once upon all who see it. The colour is white with a purplish rose

coloured bloom attaining an average diameter of 1½ ins. Last year (which will long be remembered by lovers of hardy shrubs) I measured flowers which were fully 2 ins. across. The praise so often bestowed upon *Eva Rathke* had not proved well earned in my own experience of the variety. True, its richly hued flowers are worthy of unstinted admiration, and the habit of successional blooming is a decidedly strong point. I cannot, however, forgive *Eva Rathke* for its sprawling, pithy habit of growth, which to great extent obliterates its other excellent qualities. If some successful grower would outline his treatment of this variety in *THE GARDEN*, he would earn the gratitude of myself and other northern gardeners. The Victorian Snow Bush (*Olearia Haastii*) is one of the most beautiful and reliable shrubs for gardens in the North. I cannot think of anything which so closely resembles a snow-drift as an example of this species in full bloom. The habit of growth is by no means uniform. Branches protrude here and there beyond their neighbours, gladdening the heart of those to whom anything formal is anathema. Given the opportunity, the Victorian Snow Bush will assume a semi-pendent habit, and then forms an attractive

The Blue-Green Face in Church

You see, on Saturday he painted the fence blue and the hen-run green, and he had never heard of KIT! So there was no help for it. The colour came off his hands on to his face. It wore away in a week, but . . .

It was pretty while it lasted.

KIT'S work in life is to clean the hands when ordinary soap is not strong enough. Grease and oil and paint and tar—those are the things KIT loves to move in the twinkling of an eye. Yet the after-feel is just the same as after the morning wash with toilet soap. None of the awful smell of "turps," or the soreness of pumice.

And the speed! KIT is the rub-and-a-wipe-and-it's-over-soap!

Price 6d. per Tin.

KIT the speed soap

LEVER BROTHERS LIMITED, PORT SUNLIGHT.

particular gas—carbon dioxide—which, in a pure atmosphere is very limited in quantity.

There are numerous pores in the leaf, which may be compared to those in our skins, but even thicker on the "ground," and one of their functions is to capture this gas and convey it to the laboratory inside the leaf. When thus captured it is brought in contact with other essentials, including those carried up from the roots. All these foods, however, are perfectly useless unless direct light can play on the leaves.

For further information on this subject the reader is referred to one of the many excellent text books on botany, a subject which is so necessary for gardeners to study, but which as a class they are very loath to do. I trust I have said enough to shew how very foolish it is to allow the leaves of plants to struggle in darkness.

A few years ago I had a gentleman pupil, and, among other things, we experimented on Potato-growing. In one case the rows were 3ft. apart and 15ins. between the sets in the rows. They yielded an average of 6lb. a root. An acre planted at this distance would take 11,520 sets, and this at 6lb. per root would total 30 tons 17 cwt. 16lb. No manure whatever was applied for this crop, but the ground had been well fed for the previous one. It is plain that heavy manuring would have increased the weight, though not the quality. The only fault was that many of the tubers were too large, one turned the scale at 1lb. 5oz. Most of them had been allowed to grow from one eye only.

Two or three stems would probably have produced a larger quantity of a more desirable size. I attribute this satisfactory yield entirely to the effect of the greater portion of the leaves being exposed to the sunlight.

Others of the same variety close by, planted 2ft. by 1ft. apart, were nothing like so good, and many of the tubers were small. The disease also attacked them early in the season, while the more hardy ones were scarcely injured at all.

Mr. Challis, when at Wilton, told me he obtained a greater weight of tubers when his rows were 4ft. apart than when they were 2ft. He planted Broccoli, Curly Greens, etc., between the rows, in the furrows made by pulling the earth over the Potatoes; the latter were not planted, but laid on the flat surface. There is much to be said for this plan. The Potatoes would be placed on and covered with well aerated soil, leaving furrows which would be of advantage to the Broccoli.

Where the soil was fairly good and was not disturbed after an early earthing up, I have found that, when a space of 4ft. was allowed between the rows, the roots met across these spaces at a very early stage, therefore I am confident that the plan of "hacking" and earthing up after the haulms are 5ins. or 6ins. high is very detrimental.

A few varieties bear the tubers close to the stem, but when this is not the case I prefer leaving them in a shallow furrow in order not to bury the primary leaves or needlessly to bleach the stems.

WM. TAYLOR.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Turnips.—Seed may now be sown in quantity in drills 15ins. apart and 3ins. deep. The fly is troublesome occasionally, but as this is only harmful during the seed leaf stage, it can generally be kept in check with a dusting or two of soot. Snowball is a very good variety to sow now.

Peas.—Seed of any of the main crop varieties may be sown, and if the ground has been well dug and liberally manured, flat drills about 6ins. wide will suffice. If for any reason this has not been done, trenches can be prepared similar to those for Celery, taking out the soil 2ft. or 3ft. deep and incorporating a quantity of partly rotted manure and a sprinkling of ashes from the rubbish fire. The distance between the rows will vary in accordance with the height of the Pea grown, and as a guide the distance might be the same as the height of the variety chosen. The seeds should be covered to a depth of 2ins. or 3ins. Another sowing of Broad Bean may also be made.

Beet.—A row or two of Beet may be sown, selecting a turnip-rooted variety for the first crop. A warm border is best for this sowing.

Hot-Beds are always useful for raising a few seeds, and at the same time Cucumbers can be grown thereon with considerable success. The making of a hot-bed does not require a great deal of skill, the most important item being the manure, which should be more or less "green" to get the best results. To every cartload of manure two barrowloads of leaves may be added, and the whole well mixed and turned three or four times before the bed is made. This should be 18ins. wider than the frame on all sides, the frame being placed in position when the bed has settled down. A small mound of soil should be set in the centre of each light, and when the heat is steady at about 70° the Cucumber plants may be put out. Admit a little air when the weather is suitable, but the lights ought to be closed by three o'clock.

The Flower Garden.

Polyanthus.—Seeds of this beautiful spring flower are usually sown about May, but I always prefer March for this operation, because much finer specimens are secured for planting out in September. Sow the seeds in pans or boxes containing a mixture of loam and leaf-mould, and place them in a cool greenhouse or cold frame

Like all the Primula family, germination is often slow and irregular, so if only a few seedlings appear, the pans should still be retained and kept moist. Carefully remove the seedlings and transplant them 1ft. apart in a partially shaded portion of the reserve garden. Keep them free of weeds, and if the summer proves dry, they should be afforded an occasional watering.

Aquilegias have been so improved of late years that now they are well-nigh indispensable for the flower garden. Seeds may be sown at this season as advised for Polyanthus, but they may also be sown at a later date in the open ground, and the plants will bloom next year. Where space and time can be spared, however, early sowing is to be recommended.

Mignonette should be grown by all on account of its perfume. Make the ground firm and well thin the seedlings when large enough. Mignonette will not transplant readily, so it must be sown where it is intended to flower.

Fruit Under Glass.

Strawberries.—Where plants are bearing fruits that are approaching the ripening stage a somewhat drier atmosphere should prevail, and the plants must not be kept excessively wet at the roots. When the fruits begin to colour syringing of the foliage must cease, and a little more air be admitted both day and night.

Vegetables Under Glass.

Cucumbers.—More seeds may be sown to keep up the supply of fruits. Cucumbers enjoy plenty of heat and moisture, and at this season ample use can be made of the sun to keep up the required temperature, while the syringe should be employed once or twice each day according to the weather. Plants that are fruiting will be benefited by weak liquid manure twice each week or an occasional sprinkling of artificial manure.

The Hardy Fruit Garden.

Newly-Planted Fruit Trees should be examined occasionally to ascertain if they are still firmly embedded in the soil, and that the stakes and tying material are not chafing the bark. Standard trees especially will need attention, for many a tree dies because it is loose in the soil. A mulching of partly decayed manure will assist in the formation of fibrous roots and prevent the soil from drying out.

General Work.—At this date the pruning and tying will be completed, and it is advisable to

collect all prunings and burn them, thus giving the fruit quarters a clean and tidy appearance. The hoe must be used frequently among the smaller trees to keep them free of weeds, while a watch ought always to be kept for insect pests.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Carrots.—The main crop should now be sown in shallow drills 3ins. apart. Sow very thinly so that little thinning of the crop will be required. Thinning Carrots encourages the carrot fly. Soot, lime or wood ash also helps to ward off the dreaded enemy.

Late Potatoes should be planted within the next fortnight in drills 3ins. to 3½ins. apart, according to the variety. Only immune varieties must be planted in areas in which the wart disease is present. Wood ashes scattered in the drills improve the crop.

Globe Artichokes.—Remove the protecting material, and if the ground was not mulched in the autumn, it should get a liberal dressing of farmyard manure prior to digging over the quarter. The Globe Artichoke is a gross feeder, and succulent heads cannot be produced unless the plants are liberally treated. If it is desired to make a new plantation, the quarter intended for their reception should be liberally manured and trenched. It is always easy to get side growths from the established plants to form a new plantation.

Mustard and Cress may now be raised in the open, but that raised under glass will be more tender.

Fruit Under Glass.

Early Vines.—Thinning of the fruit should commence as soon as the berries are the size of small lead shot. The bunches should not be touched with the hands, but manipulated by means of a slender forked stick. The circumference of the bunch should not be reduced. First remove all berries which have not set properly and avoid making gaps, *i.e.*, endeavour to have the distance from berry to berry as uniform as possible; the bigger shoulders should be tied up somewhat, but not so far as the horizontal.

Peaches and Nectarines.—Thin out the young shoots at an early stage, but by degrees. The basal shoot on the present year's bearing wood should never be removed if at all a normal shoot, as it is the "succession" shoot which is to bear fruit next year. If any part of a tree—through "gunning" or other cause—is deficient of young wood, allowance should be made for making good the deficiency when removing the young growths.

Vegetables Under Glass.

Tomatoes should have all side shoots promptly removed, and as flowers develop they should be tapped lightly with a rabbit's tail attached to the end of a cane. This operation should be performed in the course of the forenoon.

The Flower Garden.

Half-Hardy Annuals, if pinched immediately beyond the first or second pairs of true leaves, increase in vigour and in flowering capacity.

Roses.—The Hybrid Teas may now be pruned, and the Teas a week hence. The work of pruning completed, the beds or borders should be given a dressing of some reliable fertiliser prior to forking over the whole. If there is any suggestion of sourness or greasiness in the soil, a moderate dressing of lime should also be given.

Monibretias.—Dormant corms of these attractive border plants may now be planted out with safety, but those who adopt the plan of starting them into growth indoors, either in pots or in boxes, had better delay planting for another fortnight.

The Pleasure Grounds.

Lawns should be thoroughly swept and, if dry, rolled, prior to using the lawn mower, which, owing to the mild, open winter, will have to be done rather before the normal period.

Pruning Evergreens.—Most evergreen shrubs may now be pruned, using the knife or secateurs in preference to the hedge shears, which, unless used with great discretion, mutilate a large proportion of the retained foliage. Evergreens on walls, such as Garrya elliptica and Cotoneaster macrophylla, should also be pruned now.

Rhododendrons.—Early-flowering species, such as R. arboreum and R. Nobleman, if of reasonable dimensions, should have the spent blooms removed, and big specimens—if not previously attended to

should receive a mulching of farmyard manure, taking which, the best available leaf-mould.

CHARLES COMFORT

(Formerly Head Gardener to Mrs. Haig, Broomfield, Davidson's Mans, Midlothian).

GREENHOUSE AND CONSERVATORY.

Celosia cristata and its variety *pyramidalis* are very useful for furnishing the greenhouse, and a start may now be made with an early batch. Sow the seeds in a warm house in a temperature of 55°. When large enough to handle the young seedlings should be pricked off into pairs or shallow boxes, using a light, rich compost, and later they should be potted off singly into small pots, adding some old mushroom-bed manure to the compost. Good specimen plants can be grown in 48-sized pots. If larger specimens are required, 6in. or 7in. pots should be used for the final shift; while some of the tall-growing forms of *C. c. pyramidalis* may be placed into 8in. pots, when they should make fine specimens over 3ft. in height. These plants are subject to attacks of red spider, also begonia mite. A free use of the syringe should prevent the former and the sulphur vapouriser should be employed to combat the latter pest.

Capsicum annum in its many varieties proves very useful for the greenhouse in autumn. Besides serving for decorative work, the fruit can be used for culinary purposes. Seed should be sown at this time in a warm house, pricking off the young seedlings when they are large enough to handle. They should be grown on without any check, using a rich compost at all stages of their cultivation. Six-inch pots are a suitable size for their final shift. These plants are very subject to attack by red spider, which can be prevented by a free use of the syringe. Attacks of white fly and begonia mite must also be guarded against.

Hæmanthus Katherinæ and the hybrid *H. Andromeda* are very handsome and useful plants for the greenhouse. They are now starting into growth, and should be shaken out of their pots and repotted, clearing away dead roots and decayed matter at the base of the root-stock. They should be placed deep enough in the pots to ensure the crown of the root-stock being covered with about 2ins. of soil, as it is from the crown that new roots are mainly produced. The plants should be placed in a house with an intermediate temperature, giving them very little water at the root until they are growing freely and are well rooted into the fresh compost. As growth advances they should be given cooler conditions.

Hæmanthus coccineus is a very old garden plant, native of South Africa, and belongs to a different section of the genus and, like all the South African species, only requires ordinary greenhouse treatment at all stages of its cultivation. There are several fine South African species, but with the possible exception of *H. coccineus* and *H. albidus*, there are probably few, if any, of them in cultivation at the present day. The South African species as represented by *H. coccineus* do not require such frequent repotting as the more tropical ones; they are, in fact, best when left undisturbed for a number of years. They are usually kept dry all winter and started into growth about this time, when some of the old top soil should be removed and replaced with a top-dressing of rich compost. When growing freely the plants enjoy copious supplies of water with occasional applications of diluted liquid manure.

Gloriosa superba and *G. Rothschildiana* are generally regarded as requiring stove treatment. It is true they require warm conditions when growing, but when growth is matured and the plants are flowering they will stand in an ordinary greenhouse. Under the cooler conditions the flowers last much longer in good condition than when in a higher temperature. If not already repotted, the tubers which have been stored dry in their pots over winter, should now be turned out and repotted into suitable-sized pots according to the size of the tubers. The largest-sized tubers will require 10in. or 12in. pots. Water should be given very sparingly until they have made fresh roots and are growing strongly. As the growths lengthen they should be carefully secured to neat supports.

Crinum generally require warm house treatment, but *C. Powellii* and *C. P. album*, also *C. Moorei*, are hardy in the South and West if placed at the bottom of warm walls; but in the colder parts of the country they are well worth growing in tubs for the conservatory, or they may be planted out in beds or borders in any house from which frost can be excluded. Planted out in rich soil they produce enormous quantities of their beautiful pink and white flowers respectively

over a long period. If grown in tubs the plants require generous treatment and ample supplies of water.

Royal Botanic Gardens, Kew.

J. COULTES.

EDITOR'S TABLE

FROM Mr. W. A. Watts, St. Asaph, came to hand recently some flowers of *Narcissus* *Princess Victoria*, cut from the open on February 28th. Though carefully packed, they had evidently received rough usage in transit, but the long stems and widely expanded golden cups, heavily edged with deep orange, make this an attractive variety. The corolla segments are also a fairly bright yellow and the whole flower is light and graceful. This flower is classed as an *Incomparabilis*, but it must be very near the border line between *Barrin* and *Incomparabilis*.

A Choice Speedwell. Though seldom seen in gardens and not often in the catalogues, *Veronica peduncularis* is one of the easiest and most pleasing of the rock garden Speedwells. It is a perfectly hardy and robust perennial which throws up from its base in spring a throng of fine and elegant flower-stems some 6ins. or more in length. The blossoms are about as large as those of *V. Cataractæ*, white, lined with rose, and produced in extraordinary abundance from April to early summer. *V. peduncularis*, whose bronzed leafage is somewhat akin to that of our native *V. Chamædrys*, is a neat-habited little plant, elegant and compact in form, and one that asks for nothing beyond a cutting-back to the base in autumn.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

WATER LILIES (Dunmow).—The plants, in order to get them established quickly in their new or permanent quarters, are generally placed in baskets for the purpose. Rotted wood and sticks should not be buried in the soil before the water is added. Use a sufficient quantity of good turfy loam, whole turves in which the grass is dead, surrounding the roots with them or the baskets containing the plants. *Nymphaea laydeni purpurea* (crimson flowers freely blooming), *N. mullerae rosea* (rose-coloured flowers, heavily deep green leaves) and, for a white variety, *N. alba plennissia* are fairly soft and inexpensive.

PASSIFLORA CÆRULEA NOT FLOWERING FOR NINE YEARS (A. C. Norwich).—When grown in a warm position this *Passiflora* usually flowers very freely in the Southern Counties. In the North, and probably in our correspondent's district, the flowering may be less free, but it is unusual for nine years to elapse without flower-buds forming. In a Southern county the writer has seen plants covering large trellises and flowering profusely, afterwards opening a good crop of egg-shaped yellow fruits. We advise our correspondent to retain the plant.

CYCLAMENS AND SWEET PEAS (Mrs. H.).—When the flowering stage is passed, place the Cyclamen plants outside on a bed of ashes with good drainage. Do not apply any water, and directly the leaves have withered cut them off low down; do not pull them off, as this action would cause damage to the dormant crowns. Repot late in the summer or early in autumn, using a compost of turfy loam, sandy peat or sweet leaf-mould and a small proportion of rotted manure. Frame treatment, more moisture but very careful watering must be the rule. Top Sweet Peas so that at least four joints with sound leaves are left above soil level. Do this work several weeks before they are planted out. Sweet Peas raised last autumn and not unduly drawn up should be about 9ins. high now. Those raised early this year should be about 2ins. high.

GREENHOUSE.

AZALEA INDICA (W. W. Weybridge). After flowering, Azaleas should be placed in a warm house with a temperature of 50° to 60°, and during bright weather sprayed over several times a day to encourage free growth. As growth is completed they should be given more air and the temperature lowered. From the end of June they should be stood outdoors in an open position, standing them on a bed of ashes. About the middle of September they should be placed in a cool house. These plants do not require any pruning. Our correspondent's staggly plants are probably in bad condition at the root. Azaleas are best repotted when they are just starting into growth, using good fibrous peat with enough sand to keep it open and porous. They should be potted firmly and carefully watered until they have made plenty of new roots.

TREES AND SHRUBS.

PRUNING SOLANUM JASMINOIDES (W. Beaconsfield).—This beautiful climber does not require hard pruning, but a little shortening of the ends of the shoots, also thinning and trimming of crowded twigs to maintain a tidy appearance. This should be done during February before new growth commences. *Clematis tangutica* may also be pruned about the same time. This *Clematis* flowers on the vigorous young shoots, hence pruning should consist in removing all thin and weak growths, cutting back to firm and healthy wood.

ROSE GARDEN.

ROSES FOR PARTLY SHADED BORDERS (W. R. V. Kent).—The shade being on the north side would not be very detrimental. The drip, as our correspondent says, would do some harm in prolonged wet spells; but in normal summers it would not matter so much. Owing to the roots from the Oak trees permeating the soil of the borders, it will be necessary to lift the Roses every alternate year to clear the roots out. The *Rosa* *Rosa* would prove a satisfactory as any in the position. Distinct varieties may be grown in each bed or a mixture of colours and singles and doubles, which should be very interesting.

MISCELLANEOUS.

FLOWERS FOR IDENTIFICATION (W. W. Weybridge).—The flowers sent are those of the *Chimaphila*, which is known botanically as *Ornithogalum lactum*. It is a bulbous plant native of South Africa. The plants grow quite well under ordinary greenhouse treatment, but they generally prove rather uncertain in flowering, this probably because the bulbs do not get sufficiently ripened. Perhaps our correspondent can get bulbs from her friend in South Africa.

RHODODENDRON FOR IDENTIFICATION (A. M. Hythe).—The flower sent for identification was *Rhododendron Rosa Mundi*. By adding plenty of coarse grit and a little peat and leaf-mould most *Rhododendrons* will thrive in clay soils if lime is absent. The following will certainly grow where the variety *Rosa Mundi* thrives; *Chimaphila* *White*, *Noblesium*, *Princess de Sagan*, *Prince Camille de Rohan*, and *The Countess Chevalier Felix de Sauvage*.

RAMONDIA NATALIE (W. S. C.).—This plant is not found in the Caputians. Its home is in Serbia, one of the localities being Jelasnica, east of Nis, and it is also found along the Sava-Albanian frontier. Both *R. serbica* and *R. Natalie* are found at Jelasnica. If our correspondent wishes, we can, no doubt, put him in touch with someone out there who will direct him to the spot.

ACETYLENE REFUSE (C. R. Manchester).—The refuse from the acetylene generating plant is, after six weeks' exposure to the weather, practically the same as slaked lime which has been similarly exposed. It may be usefully and safely applied whenever lime is required in the garden at the rate of half a bushel to each square rod of soil. The best time to use it is in winter, and the dressing should suffice for three years.

BULBS FOR IDENTIFICATION (Miss W. Newbury).—The bulbs sent are a species of *Hæmanthus*. It is impossible to say which species this is in the present condition of the bulbs. *Hæmanthus* species require a temperature of from 50° to 60° during the growing season. They should be potted in a mixture of fibrous loam and peat with plenty of sand added. After they have made full growth and show signs of turning colour, water should be given sparingly, and the bulbs eventually allowed to rest. On showing signs of growth water must be again supplied. They may be grown in a cool greenhouse or even in the window of a living room. Propagation is effected by means of offsets, which may be taken off and potted up in the mixture mentioned above.

ASHES AND POULTRY MANURE ("Florence").—The ashes should not be injurious to the garden unless the soil is a very light one, but would be safer if allowed to be washed well by the rain before being put into the poultry house. The droppings should be very valuable for use as manure, but it should be remembered that they should be kept dry after they are removed from the house until they are used, and that they are about eight times as strong as stable manure.

SPRINGTIME.

There are few Spring-tide flowers which have not found a poet to celebrate their charms, but Spring vegetables still lack a laureate. Here is an opening for our neo-Georgian poets. As a stimulus, we shall be pleased to supply them, or the less poetical, with fine three year old plants of Connover's Colossal Asparagus at 22/6 100, carriage and packing free, and planting should be done at once.

Beware of Imitations.

The fresh greenery, which is in Nature always a feature of the surroundings of fairly sheltered waterfalls, forms an admirable contrast to the

more austere vegetation of the cliffs and banks of our rock garden, while the waterside vegetation below adds another equally delightful element.

THE TREND OF MODERN GARDENING

WHEN one considers how easily we parted with the carpet bedding style of gardening which prevailed in mid-Victorian days, it comes as somewhat of a surprise to realise that the conventional herbaceous border is still with us and alive and well. This not only because the latter is in many respects no less formal than the old bedded-out arrangement, but also because of the great expense that is entailed in its upkeep. In its orthodox form there is no part of the garden so costly to maintain as a herbaceous border, both in regard to material and labour. Yet, while so many gardens, large and small, are still bearing unmistakable indications that wages and general maintenance remain high, that portion of them which entails the heaviest outlay in time and money is suffered to remain.

There is, however, another point to be considered. I have drawn a parallel between the herbaceous border and the formally laid-out bed which may seem unjustifiable to some; but, as a matter of fact, there are probably not many people, among those who really think about such things, to whom the average border of perennials is the satisfaction that one is led to assume that it is. Indeed, there are symptoms which shew that a revolt against the border of this kind has already set in. In not a few good gardens it has already ceased to exist, and not only on the score of expense, nor yet because its undoubtedly splendid effect has produced a sense of satiety that is shared by owner and gardener alike. The typical herbaceous border seems likely to follow the carpet-bed because, like the latter, it is wanting in those attributes which are the final and enduring test in all sound gardening, viz., interest in the individual plant rather than the mass; a felicitous treatment of subjects which is the antithesis of formal arrangement; and the impression of permanence, which is one of the greatest lessons we may learn from plants in the wild state and the lack of which is the herbaceous border's most notable failing.

A momentary consideration will reveal the fact that although the bulk of the plants with which the average herbaceous border is made are termed perennials, they are less permanent in one sense than a bed of annuals or "half-hardys." That is to say, the vast majority of them have but a comparatively brief flowering period, which means that gaps in the ranks must be filled up or grown over by others set in with that object in view. Then, most of our hardy perennials do forfeit their claim to what is suggested by that term by demanding frequent lifting, breaking-up and replanting. That they would prove their perenniality without this attention may be true enough, but in so doing they would quickly deteriorate and they would lose their characteristic vigour and which Wherefore, regarded from such points of view, the border of perennials is of anything but permanent nature. It is much more akin to the foliage of a conservatory than anything else in the garden.

It may be thought that I lay too much stress on this matter of permanency, or the lack of it, to anyone who gives the subject a thought. But it is manifest that therein lies the essential difference between the gardener who plants for a permanent bed or a border, his sole object being to preserve a certain definite display for a definite

period and the man who puts in a plant or a tree which he hopes will become established and remain "a joy for ever," not as a part of a whole, but for its own sake. The one may be fully justified in maintaining that he derives as much pleasure out of his squad of Tulips or carefully screened fancy Pansies as the other gets from his odd patches of Anemone and Primula interspersed with Rose species and a few other choice shrubs, but the sentiments which inspire each of these respectively are as wide apart as the Poles.

The sort of border which promises to supplant the orthodox type is furnished with individual plants rather than groups. I have no quarrel with the latter where they are desirable, as often they are, but would avoid them where they are to be the whole what the marble chips are to a piece of mosaic. There are fine old gardens in this country where almost every plant or shrub is an individual and something more. It possesses some special history or interest in addition to its own peculiar beauty or merit, and rather than enthuse over the latest creation of the hybridist's art the owner of such a garden will, as likely as not, point out with keener pride some old variety or species one of whose most cherished attributes is that it is "out of cultivation." We may not all be able to fill our borders with rare treasures, nor would it be desirable to do so. A new Delphinium of merit has as much right to a place in our soil as a bush of Lavender which has been in cultivation with us for nearly four hundred years.

However, to describe the lay-out or the contents of an informal border would be hardly practicable, for each one will be the outcome of the owner's individual taste, a reflection of his individuality, and here, again, you have a clear line of demarcation between the herbaceous and what I have called, in the absence of a better term, the mixed border. The former is, generally speaking, manifestly the result of a carefully worked-out design, possibly the exact replica of one of the map-like plans one sees in nurserymen's catalogues, whereas the latter is as far removed from any indication of such design as is a stretch of moorland or a hedgerow bank. Even though maturity and permanence may be among the most abiding charms of this unconventional border of plants and shrubs, grasses and bulbous things, it is the absence of conscious effort which is, after all, its happiest feature.

A. T. JOHNSON.

TWO EARLY-FLOWERING CHINESE RHODODENDRONS

TWO first-rate Rhododendrons in flower now in these gardens are *RR. calophytum* and *sutchuenense*. They are both Chinese species, and were discovered on the vast mountain ranges of that country by the collector Wilson during his 1904 expedition. *R. calophytum* had previously been found by the Abbé David in Tibet, and *R. sutchuenense* by the Abbé Farges in the province of Hupeh in China. Probably, most of the plants now growing in various gardens are the result of seeds sent home by Wilson.

They are both species with large, handsome foliage. *R. calophytum* has lanceolate leaves

THE ROSY PINK RHODODENDRON SUTCHUENENSE.

from 12ins. to 15ins. in length and nearly 3ins. broad in the middle. The flower truss is large and loosely built up of about twenty flowers; the buds are pink, opening somewhat paler, and fading off almost to white with age. The corolla is deeply lobed and has crimson spots on the upper interior portion. These spots run into a large crimson blotch at the base. The stamens are numerous. I have counted twenty on one flower. A remarkable feature is the big greenish yellow stigma. This is almost a quarter of an inch in diameter! The flowers have the merit of being agreeably scented.

R. sutchuenense is quite a different plant to the preceding. The foliage is slightly glaucous, up to 12ins. in length, bluntly pointed, and about 2ins. wide nearly the whole length of the leaf. The flower-truss is large, fairly compact and made up of about eighteen flowers; the truss is in most

cases a little flat owing to what should be the terminal failing to develop or just forming a few bracts instead of a flower. Now and then a complete oval-shaped truss can be found. The flowers are rosy pink, paler inside and heavily spotted. The corolla is waved, which gives the trusses a distinctly fringed appearance.

Both species are good sturdy growers, only asking for shelter from wind, shade from excessive sun, and a natural canopy of boughs above them as a slight winter protection—conditions which usually obtain by the side of woodland walks and similar places. The foliage of both is very quickly affected by frost, a few degrees being sufficient to make the leaves curl up into the shape of a lead pencil. The leaves of *R. calophytum* will curl up in a similar way if the plants get excessively dry during the summer months. Frost, however, does not appear to harm them, and they seem to be quite hardy in Surrey. Flowering as they do early in March, frost does, however, sometimes spoil the flowers. *R. calophytum* has one other drawback. The leaves surrounding the flower-truss all point upwards and form a sort of basin with the flowers at the bottom. So much is this the case that the upper flowers on a bush, say, 6 ft. high, would be almost hidden. Here is a remedy. Plant it on a slope with a path well above so that one looks down upon it.

Some authorities say these two species are closely related, but as a practical grower and a novice at botany I fail to see where the relationship comes in. That, however, is a small point. What is more to the point is that these are two of the finest really hardy *Rhododendrons* we have had from China.

Holmwood, Surrey.

S. W. P.

A NEW CHINESE PRIMROSE

P *PRIMULA calciphila* is a very interesting Chinese Primrose which has been in flower in the conservatory at Kew since early January. It was originally discovered by Professor A. Henry on limestone hills near Ichang about one thousand miles from the mouth of the Yangtse Kiang River. Seeds were sent home and the plant eventually flowered. It was then thought to be the original wild type of *Primula sinensis*, the well known Chinese *Primula* of greenhouses.

Afterwards Henry's plants were lost to cultivation, but seeds were again collected by E. H. Wilson on the same site near Ichang, and from them were raised the plants now flowering. From the fact that it would not hybridise with the garden forms of *P. sinensis* and from certain structural differences, especially in the calyx, doubts were expressed as to its being the wild type of that species, among others by Professor Bateson of the John Innes Institute at Merton. Further investigation has shown that it is specifically distinct, and it has been named as above, the specific name referring to its love of lime. It is a very pretty plant, and for eight weeks the group of fifty or sixty plants at Kew gave a charming effect. In size and arrangement the flowers resemble those of the common Chinese *Primula*, but are more elegantly disposed. The colour is a pale blue. Cultivated plants produce seed freely if artificially fertilised, and there seems no reason why it should not become a popular plant for winter use in cool greenhouses. Lime in the soil, however, seems essential to its success. Apparently the real wild type of *Primula sinensis* has still to be discovered.

W. J. BLAIR.

NOTES ON BULBS

A NEW DUTCH HYACINTH. — Everyone who has seen the new Hyacinth, Tubergen's Scarlet, in our greenhouse this spring has been taken with its beautiful colouring. Beside it *Roi des Belges* and *Garibaldi* must veil their faces. They

than the majority of its brethren which only hold courtesy titles.

CROCUS SPECIES VERSUS DUTCH CROCUSES. — Not only in *THE GARDEN* but in the pages of several other papers devoted to gardening I have lately seen notes "cracking up" *Crocus* species.

May I hope that for once in a way the trite saying of La Rochefoucauld may be wrong and that the advice to try them may inspire the conduct of readers when bulb-order time next comes round. The quintet I like to see in my own garden are *biflorus*, *Susianus*, *Imperati*, *Tommasianus* and *Sieberi*. They are all — even the largest of them, *Imperati* — ducky little creatures, and in my humble opinion more than hold their own in beauty and grace when compared with the larger and coarser-looking so-called Dutch varieties. A Monseigneur recently told me a good tale. Immediately after war broke out in 1914 he happened to be walking on one of the Devonshire moors when he came across an old roadman to whom he told the news, remarking that he supposed England and Germany would soon be fighting. "Eh, mister, I hope they'll have a fine day for it." Perhaps there are some who know as little about my quintet as the countryman knew of war, and will wonder why I wish they will have a genial early spring in every

PINK TRUMPET NARCISSUS MRS. R. O. BACKHOUSE.

look dowdy. Everyone passed them over in silence, which, if it be golden itself, means so often in similar circumstances that the unnoticed are but as a far baser metal. The new-comer is a sport from the old deep claret-coloured *Distinction*. Thus no one must expect a monster spike like that of *Jacques*, nor bells of the size of the large white *Corregio*. It is, however, amenable to undergoing the process of being "prepared" for extra early blooming, and was one of the varieties that graced the show at Haarlem on December 23, 1922, of which there were some pictures in *THE GARDEN* for February 10, page 71.

HYACINTH PHENEMAN. —

"Should auld acquaintance be forgot,

And never brought to mind?"

We do, alas! sometimes forget. Until I renewed my acquaintance with *Pheneman* this spring I had not seen it for a very long time, and its distinct and effective colouring had passed out of my mind. "Blues" rather overwhelm us in bulb lists. Between the ultra dark *Menehik* and the pretty pale *Johan* there is a multitude of bewildering names, and "which shall I order?" is, in consequence, for many a big puzzle. I think the large-bellied *Pheneman* with its sturdy-looking but somewhat loosely clothed spike might be given a trial. It is, too, far more of a real blue

garden when they make their *début*. It is because they can be counted on to bloom long before the year is three months old even in cold Midland gardens, and one knows what cruel buffetings they often have to endure. It is marvellous how they come through it all. One must not judge them by the Dutch.

IRIS RETICULATA. — I am so glad writers have been singing the praises of this lovely *Iris* when it is grown in a cold house or frame in pots. If instead of pots small, round, low pans are available, the effect is still more pleasing, and it is worth while taking a little trouble to procure them. I wish I could tell readers where they can be had, but I fear I have lost the address. I wish someone who reads these notes and grows *reticulata* in pots, would tell us how to preserve the bulbs after they have done flowering. Unfortunately, with us, potting is the equivalent to a long-drawn-out sentence of death. Empty husks are all that we find when the bulbs come to be turned out.

PINK TRUMPET NARCISSUS. — Judging by enquiries which we receive, much interest is being taken in the pink trumpet *Narcissus* by flower-lovers who, apparently, have never seen them. The variety *Mrs. R. O. Backhouse*, illustrated herewith, is the best known, and the picture gives a good idea of the shape of the flower, which is

on the small side but very refined. The colouring is very pale, amounting to little more than a suffusion of salmony or perhaps coral pink. The blossoms are very beautiful when seen alone, but are easily overlooked in a large mixed exhibit including such as the giant yellow trumpets,

Sea Nymph, which attracted a certain amount of notice at a recent meeting of the Royal Horticultural Society, is not very dissimilar in shape or colouring. They bear evident relationship to the Leedsli section, will probably like similar conditions, and certainly associate well with them.

THE TORCH LILIES

THE *Kniphofia* family is just on the border-line of hardiness in Britain, so that while some species and hybrids are hardy (at least in average winters) in all but the coldest districts, others are useless outdoors except near our seaboard. There is, however, so great and so fine a variety of forms which are comparatively hardy that we need scarcely bother about the tender kinds.

Spring planting is naturally desirable, but this should not be left too late, otherwise the plants do not have time to re-establish themselves before summer comes with its very possible drought. The variety *Rouge et Souffre* illustrated below bears magnificent coral-red spikes which change, as the blossoms expand, to clear yellow. The spikes as shown are about roins. in length, and the stems, while stout enough to carry the heads (pokers as country folk often call them), have not the coarseness characteristic of many of the forms of *Kniphofia Uvaria*.

Not all the *Uvaria* (aloides) forms have coarse stems. *K. U. nobilis* is still one of the finest of Torch Lilies, with almost scarlet flowers changing to soft yellow. Probably the finest of the giant yellow forms is *C. M. Prichard*, which also received an award last year, but the stately *Ochelsk*, the even taller *Star of Baden-Baden* and the orange-yellow *Ophir* are all magnificent.

The majority of Torch Lilies are herbaceous, some being deciduous, but the greater number having linear foliage which persists through the winter. There is one small group, however, which has a persistent gradually lengthening stem and very much stiffer, semi-succulent foliage, so that the whole plant approaches the shrubby *Yuccas* in appearance. Three species of this group are *KK. caulescens*, *Tysonii* and *Northia*. The foliage in each case is glaucous and the habit of the plants much the same, but whereas *K. caulescens* has short, compact flower-stems with flowers opening a virulent brick red, changing

to greenish ivory and very difficult to associate with other flowers, *K. Northia* has long, handsome, soft yellow spikes with the unexpanded buds merely tinged with red. *K. Tysonii* is a June-flowering species with fine spikes of orange-scarlet and primrose yellow; this is a grand plant, but needs care when associating it with other flowers, as the colouring is rather strident. Experience suggests that *K. caulescens* is the hardiest of the trio, but the other species have been with us but a comparatively few years and they may probably acclimatise satisfactorily.

Kniphofia multiflora, also illustrated, is a white-flowered species which, itself only half-hardy, will doubtless leave a mark in time on the harder section of the genus. With its narrow spike of comparatively long protruding stamens it hardly strikes one as a Torch Lily, though the long, broad leaves are very characteristic of the genus. *K. modesta* is another white-flowered species.

Kniphofia paniculata is only hardy in very favoured localities, and the cross-breeds between this species and forms of *K. Uvaria*, though very grass-like and elegant in foliage, fine stemmed and beautiful when in flower, are none too hardy. They are so suitable for rockwork, however, that they should be largely planted even if special protection has to be afforded in winter. They are even more elegant than the dwarf *K. Macowanii* with orange red blossoms, which is, however, hardy enough. The rather attractive *corallina* is a hybrid between *KK. Macowanii* and *Uvaria*,

THE WHITE-FLOWERED KNIPHOFIA MULTIFLORA.

CORAL AND SOFT GOLD, KNIPHOFIA ROUGE ET SOUFFRE.

soil is bigger and stronger than the former, and rather more refined than the latter species.

Light, well drained soils suit the Torch Times best, and these should not be over-manured for two reasons. Over-rich soil does not make for floriferousness, and it does make for softness and

consequent inability to withstand the rigours of an English winter. Lunged disease, too, is apt to attack plants which have been overfed. When all is said too much can be made of the supposed tenderness of the Torch Times. Most of the forms and hybrids of *K. Uvaria* will withstand more

frost than any of the *Yuccas* except *YY. filamentosa* and *flaccida*. In districts where snow is commonly experienced some of the foliage may be tied up to protect the crowns, but care should be taken to see that this does not expose the base of the plant to wind frost.

SOME FACTS ABOUT THE CINERARIA

THIS is a favourable season to take stock of the *Cineraria*, inasmuch as the various strains can now be seen in flower and the time is fast approaching when seed should be sown for late autumn and winter flowering. For spring display the end of June till the middle of July is the best period to put in the seeds.

A good type of the florists' *Cineraria* is illustrated below. These old-fashioned flowers have of recent years had their colour range enlarged considerably, so that, in addition to the old and well known dark blues and velvety rich purples, there are now china blue shades, pure whites, old rose tones and a particularly vivid red shade usually described as scarlet. Many gardeners fight shy of this last, remembering the original German strain of this colour called *Matador*, which left much to be desired as regards habit and form of flower. Messrs. Sutton's present "scarlet" strain is practically as good in every respect as the blues, whites and pinks.

The next addition to the large-flowered class will be the very soft yellow recently exhibited by Messrs. Sutton at the Royal Horticultural Hall, which, while certainly a great improvement

on a Continental strain of similar colouring distributed before the war, will not be everybody's flower. The habit of the plant and shape of the flower are practically identical with Sutton's *Superb White Single*—which is to say that they are excellent. Soft yellow is certainly an extremely useful colour for harmonising otherwise conflicting shades, but this is less necessary with plants in pots under glass, which may be moved about at will, than in the herbaceous border.

Quite apart from these large-flowered exhibition sorts there is quite a variety of distinct types of *Cineraria*, all of which have special merit for some particular purpose. There are tall *Star* forms and dwarf ones and cactus-flowered *Stars*. Incidentally, there is a compact-habited, large-flowered strain with cactus-shaped flowers. Of all the light, graceful forms, however, the strain called *Feltham Beauty* takes the palm for any grace and delicate colouring. The plants of this strain are more spreading in habit than the true *Stars*—they are usually considerably wider than high—the blossoms are larger, the petals broader and more even, but not overlapping, and the central disc, which is proportionately small, is white, whereas in other strains it is dark. The effect which this has on

the apparent lightness of the flower, even on the total effect of the colouring, must be seen to be believed. From a decorative point of view the *Feltham Beauty* strain is the most noteworthy of all races of *Cineraria*.

There is one other variety of small-flowered *Cineraria*—it is not a *Star*—which is very much worthy of mention; this is Sutton's *Forget-me-not Blue*. Not only is the colouring very beautiful (it is a little too vivid for a *Forget-me-not*), but the habit of the plant is very desirable. The head of blossoms is carried just high enough entirely to clear the foliage, which makes this variety much more decorative than the large-flowered sorts. There are, however, many who still cherish affection for the large-flowered varieties and for the brilliant purple and white, blue and white, and crimson and white sorts in particular. Kelway's *Perfect Model* strain of these flowers is wonderfully good and obtainable from most reputable seedsmen throughout the country.

The first half of April is not too soon to sow seeds if the plants are required to be in blossom by Christmas, for the *Cineraria* is a plant which abhors forcing. A compost consisting of three parts fibrous loam, two parts leaf-soil and one part sharp

A TYPICAL FLORISTS' CINERARIA.

THE WHITE-EYED CINERARIA, FELTHAM BEAUTY.

silver sand should suit them well. The *Cineraria* abhors a dry atmosphere, especially when accompanied by heat. Sow the seeds thinly in pans placed in a shady corner of a cool greenhouse, prick off as soon as large enough into pans or boxes of compost similar to that recommended for the seeds, and transfer them as soon as they touch into "large 60" pots. They should now be moved to a cold frame or pit facing north, there to remain until autumn. Repotting must, of course, take place as the pots become full of roots. Six-inch ("12") pots are large enough for most purposes and much handier than larger sizes, but the 7 in. ("24") size may be necessary if the plants are intended for exhibition. They should be potted firmly at all stages (but not heavily rammed like hard-wooded plants), and should not be fed at all until the flower-stems begin to shew. It is true that larger plants can be obtained by earlier feeding, but these are apt to be unduly soft, so that the flowers are weak and misshapen, the trusses loose and straggly, and the foliage becomes limp and wilts on the slightest provocation.

Throughout the period of growth shade must be afforded from the direct rays of the sun, but not from other light. A little thoroughly decayed dung and fine crushed bones may be used in the compost for the final potting. It is very important that the plants should be kept free from insect pests, especially green fly and the leaf-mining maggot. To spray efficiently under the leaves means turning all the pots on their sides, so that frequent fumigation is practically a necessity with this plant. It should not be neglected. Early raised plants are far less likely to be troubled when mature with the leaf-miner than the later batch which flowers in spring. Despite all precautions a few young plants may shew the characteristic transparent tunnels in summer. If a sharp look-out is kept, however, these are soon detected and the offenders caught. For feeding purposes an infusion of sheep dung is excellent. It should be used weak and, as already mentioned, not until the plants are mature. It may be alternated with weak soot-water.

GLORIOSA SUPERBA

If put in a warm, moist temperature in the stove, these useful bulbs grow with great freedom and produce a wealth of flowers for many weeks in succession. It is a native of the warmer climes and was introduced more than two centuries ago, and although commonly called *Gloriosa*, its true name is *Clynostylis*, a name rarely used. It may well be classed among the most useful of stove plants, both for covering trellises and for its flowers. The culture is not difficult, and anyone having a plant stove can grow it with ease. Our plants are grown and trained to wires on the back of the stove, and usually grow to the height of 10 ft. or 12 ft. In this position, though far from the glass, they thrive well and produce very large quantities of flowers. In March the bulbs are carefully shaken out of the old pots and repotted in a mixture of peat, loam and plenty of grit. The soil is for some time kept very sparingly watered, but when plenty of roots have formed, water is more liberally supplied, and weak manure-water is given at intervals during the growing period. Drainage must be good, and the pots clean and dry when the repotting is being done. We usually place four or five bulbs in 10-in or 12-in pots, and when the growing season is drawing to an end and the leaves begin to change colour, water is gradually lessened till the soil becomes quite dry, and the pots are then kept in a warm place till the following March.

H. MARKHAM.

THE "GAZEWAY"

ON the main Portsmouth Road at Surbiton Messrs. W. H. Gaze and Sons of Kingston-on-Thames and 10, Conduit Street, London, have modernised an Early Victorian house

and display there a number of very interesting ideas in furnishing which are, no doubt, intended to appeal to many tastes. Not only are various schemes of decoration carried out, but the latest labour-saving appliances are demonstrated there.

Attached to the house is some six acres of ground which, when Messrs. Gaze took over the place at the beginning of 1922, was absolutely derelict. Except for portions reserved as a nursery and for the well known Gaze hard tennis court, all this land has been laid out as model gardens.

This has been managed in a distinctly clever manner. The house itself is of considerable size and some of the gardens are of suitable proportions for a quite small villa. It needed, then, considerable ingenuity so to arrange the gardens that they should bear any relationship to the house. That the view from the house is quite a pleasing one reflects great credit on the garden-design department.

Looking eastwards from the loggia immediately behind the house, there is a perfectly plain stretch of lawn in the immediate foreground which, further back, has wide borders of herbaceous perennials, the whole terminating in a semi-circular arrangement of steps and walling, which latter supports a curvilinear pergola on higher ground. Water in the shape of a dipping well, a circular pond and a narrow rill with stone coping is also introduced, and above the dipping well the vista carries through between the piers of the pergola to the extremity of the grounds in that direction. The pergola in question is of very elegant design, but too slender for many positions. It looks quite well in the position in which it is placed. Careful inspection shews that some of the piers are genuine old stone and others modern reproductions, thus affording an interesting comparison for those in doubt which to buy.

When one comes to traverse the various formal and semi-formal gardens, the rose and moraine

gardens, herbaceous borders and children's garden, one begins to appreciate what such a range of samples would mean to the average man. Like the draper or the haberdasher, Messrs. Gaze cater for a wide variety of tastes, not only in the gardens

CASCADE IN THE "GAZEWAY" ROCK-GARDEN.

but indoors. There are so many gardens here and so many features that most people could quickly form an idea of what they wanted. Not that one can take bits of several schemes and stick them together and make a design of course, but one could describe what one likes or dislikes to Messrs. Gaze's garden architect in attendance and leave him to work out a scheme from the insight thus afforded into his client's tastes.

One of the most interesting features is the rock and water garden in the setting of greensward now generally approved.

The accompanying illustration shews the cascade in this rock garden, which is a very pleasing piece of work in itself and, considering that it was not commenced until 1922, a marvellously successful piece of planting.

Certain of the gardens are open to the objection of being a trifle banal—there is far too much crazy paving employed, for instance—but, well! Some people like crazy paving, and perhaps there is no harm in shewing what it looks like when laid. The various sorts of rectangular paving are also largely used, and it is thus easy to compare the effects produced.

ON DESIGNING A GARDEN

TO plan and make a garden is a pastime that appeals very much to most of us. The love of plants and the soil is a natural one, and the rich brown colour and clean, healthy scent of newly turned ground is delightful to nearly all of us. In larger gardens much of the work must be done by gardeners, but true plant-lovers like digging and planting, and the pleasure of seeing the results of their own handiwork.

The gardens of to-day are carefully thought out, and are generally in their results much more beautiful than was formerly the case. They may be formal or informal, stately or picturesque, as seems most fitting, but whatever the style, one should feel in any garden that its own particular character has been developed in the most effective way.

Whether large or small, any grounds should contain, in balanced arrangement, as many of the different kinds of gardens as the nature of the site makes reasonable. Some sort of formal terrace or terraces around the house are generally necessary; they are the connecting link between the residence and the gardens proper, and if not present in some form an essential feature is felt to be missing.

Of the different gardens that one may have, several may be classed as indispensable. Everyone will wish to possess a rose garden, and almost everyone will want herbaceous borders; while a collection of flowering and foliage trees and shrubs may, in spring and early summer, form some of the most beautiful and typically English scenes it is possible to have. Rock gardens are always interesting, and when well placed and well made may be very beautiful. Their site, however, needs careful choosing, for, of all gardens, a rock garden must fit happily into its surroundings, otherwise it is better far to do without it. This may be said to apply to greater or less extent to all types of garden, but a formal garden is obviously designed and made, whereas the appearance of a rock garden should arouse the feeling that it has grown there naturally and that no other sort of garden could possibly be in that place.

It has sometimes occurred to me that a great number of people miss a lot of the pleasure of garden making. They like plants of all kinds, but they like them as separate plants, and often entirely miss the added delight of putting them in their right place in the garden. In working or playing with them, whichever way you like to have it, they should, in fact, be used as an artist uses the paint on his canvas, every bit of form and every touch of colour subservient to and helping to make the finished picture. This is the way to use plants, unless you are, or wish to be, a collector, and like to see them in straight rows, each plant with every atom of its natural beauty carefully staked away. I think that even collections should be in groups and each group as big as the space allows.

Some people possess a happy instinct so far as the design and arrangement of gardens is concerned. The quality most essential to success in such work and the quality the evidence of which I have found most often missing in gardens I have visited is the sense of proportion. Many people realise this, yet I have often been asked to treat a certain area of ground, my client saying "we can go farther if necessary when this is done," apparently oblivious of the fact that to extend the gardens in any particular direction might very probably entail the alteration of every garden already made on that axial line. For the plant-lover the choosing of trees, shrubs, and

plants is an engrossing task. The choice and use of plants are inseparably interwoven. Certain plants belong to certain parts of the garden, and one feels instinctively that they could only be used in particular places and for certain kinds of planting. Shrubs, especially those of beautiful habit of growth, seldom, if ever, look well in straight borders, and, generally, the more informal the method of planting the better. As with most other plants, the greater number of shrubs should be planted in masses. To see this it is only necessary to compare the effect of a glowing bank of *Berberis Thunbergii* in autumn, a stretch of *Cotoneaster horizontalis*, or a foamy mass of *Cytisus albus* or *C. praecox* in flower, or seas of *Rhododendrons*, with single specimens of these same plants dotted in a mixed shrubbery. In fact, the difference between single plants and masses of the same thing is often so wonderful that it is difficult to believe they are the same.

Do not plant uninteresting trees, shrubs or plants. There are so many that are really beautiful that the largest garden could scarcely contain them all, at any rate in sufficient numbers to make the most effective planting. It is a sense, partly intuitive, partly the result of training and constantly observing plants, that tells us how and where to use certain plants and what kinds are best for certain positions.

Quite a large number of plants may be grown under any ordinary conditions, but no one would think of planting the *Candelabra Primulas*,

to the ideas of the person using it. Generally, however, it may be taken to mean a happy combination of formal walks, flower borders filled with old-fashioned perennials—only these should be the best varieties—clipped hedges, and, it may be, flagged terraces and walks.

As well as Old English one might give a garden the light, graceful feeling that one associates with French art of a certain period, or it can be made Italian in feeling or treated in many other ways. One may take any keynote, English, French, Italian or whatever one likes, and build upon it any number of variations, remembering always that a certain fitness of relation must govern everything one does and that there must be a *motif*—generally the architectural character of the house.

In some way one must always contrive a culminating point, which must be approached with increasing interest. From it one must go to unexpected but lesser features, being surprised and pleased to the limits of the grounds.

Between the house and its immediate terraces and surroundings and this principal feature in any set of gardens there should be a pause, as in a good musical composition one must be prepared for, and lead gradually to the point of greatest interest.

It is also interesting to take the best of whatever old work is most suitable, and by judgment and good taste make of it a beautiful adaptation for your own grounds. For a classic villa the principal outdoor feature might well be a sunk Italian garden; the classic feeling can then be repeated in the architecture of temples, pavilions

FROM ROSE GARDEN TO UPPER LAWNS AT CRANBOURNE COURT.

Japanese Irises or *Myosotis palustris*, for example, or any other moisture-loving plants on dry banks or in any position other than low down in damp ground or near water.

It would be interesting to make your gardens, or one of them, of a certain period, or to give it a definite character. What is known as the Old English style is probably likely to relate best to most surroundings, but Old English is a vague term and varies greatly in its meaning according

and other buildings, and even by the form and placing of the seats. Probably, however, gardens the most in harmony with present-day English domestic architecture, when the tendency is to have comfortable but smaller houses, are a happy union of formal and informal, without any too marked influence from older design. In such a set of gardens the formal alleys and terraces adjoining the residence, and whatever other formal gardens there might be, should merge into any

rock and wild gardens and natural groupings of trees and shrubs. Gardens entirely formal in design, beautiful as they often may be in themselves, often leave an unsatisfied feeling, as if they were in some way or other incomplete.

The illustration on the preceding page depicts

a portion of the garden at Cranbourne Court, Windsor Forest, the residence of Sir Charles Shaw, and shews the more or less natural use of trees, shrubs and lawns, and the effect that may be obtained with them.

PERCY S. CANE.

CORRESPONDENCE

PRIMULUS HYBRID GLADIOLI.

"J. L. G." would like his list of these added to. May I mention a few which I think are hard to beat? I will not include any that I have not grown for at least three years. Jewel, a daintily beautiful flower of clear salmon pink with golden yellow throat; Gold Drop, large ruffled yellow with red lines in throat; Rosalia, yellow, blushed orange, lower petals golden yellow, much the best of its particular colour, but not always a perfect spike; Topaz, an unusual combination of salmon pink and buff; Myra, a giant-flowered variety in this section, but not to be overlooked; Primunilla, always a favourite where grown, but only just coming down in price. Of the more recent introductions I think Bobolink, Eden, Nightingale, Shell Pink, Sonia and Twinkles are among the best. Of the cut and come again varieties (they are all free flowering) I would mention Faun, Linton, Rodano, Sweet Ora, Utopia and Zenobia as being particularly useful. Is the demand for these flowers increasing? Judging from a list received this (March 15) morning it would appear to be so, as several of the varieties are therein marked "sold."—G. C.

ROSE MARECHAL NIEL.

THE parentage of Maréchal Niel is usually given as follows: Raised by Pradel, 1864. Solfaterre × Isabelle Gray.—S. W. BURGESS, Tonbridge.

THE LATE REV. W. WILKS.

AT the meeting of the Council of the Royal Horticultural Society on Tuesday, March 13, Lord Lambourne spoke of the loss which the Society and the Council had incurred through the death of the Rev. W. Wilks. He said that they were meeting under the shadow of a great sorrow, for Mr. Wilks had meant much to the well-being of the Society. His great personality and his intense activity in the stormy days of the Society's early life had been of the greatest value. His ripe judgment and experience had always been at the call of anyone who wished to avail himself of them and, though he was very determined in his opinions, he never hurt anyone's feelings, and his good temper and tact even in the most difficult positions had been of the greatest possible use. Lord Lambourne then moved the following resolution, which was adopted in silence: "The Council has heard with the deepest regret of the death of Mr. Wilks, for thirty-two years secretary of the Society. It wishes to place on record its appreciation of the great work which he did for the Society and of the untiring energy with which he was always ready to further its best interests. Its members feel that they have lost a good friend, and beg to offer their deep sympathy to his relations."—W. R. FYNES, *Secretary, R.H.S.*

CODONOPSIS OVATA.

IN the issue of March 10 a beautiful illustration of *Codonopsis ovata* is given on page 124. Does your correspondent grow the far more graceful plant, variety *himalayana*? Its paler blue flowers have a beautiful combination of

white and orange inside. It is of dwarfer habit than *C. ovata*. If possible, both should be planted on an elevated part of the rock garden, near a path to allow examination of the flowers, which, unfortunately, have an unpleasant smell. The

VIOLA CALCARATA IN THE ALPS.

attraction *Codonopsis* has for slugs may be the reason it is so seldom seen in gardens—W. P. M., *Willbrook*.

THE interesting article in THE GARDEN on *Codonopsis ovata* does not mention the exquisite colour of the inside of the bell. Perhaps its unpleasant smell when bruised may explain its being seldom grown in gardens.—T. A. STURGE.

IS not one reason why this fine plant is comparatively seldom grown because it is not very long-lived in many soils? Also it is of a brittle nature and is liable to be snapped off at the base of the stem by sudden gusts of wind just when it is in full flower. Fortunately, it is so easily raised from seed that it can be readily replaced. It cannot be termed a particularly showy plant, but the exquisite colouring of the interior of the "bell" renders it one of the most fascinating of all the great *Campanula* order. The late Mr. Albert Wood (whose garden at Sutton Coldfield was so full of choice plants) used to delight especially in shewing this plant to visitors. He called it the "Oh! Flower" because he said the introduction to its amazing internal colour scheme invariably evoked an "Oh!" of astonishment from the beholder. One word of warning—do not be beguiled by the beauty of the flowers to pick them, for the broken stem of *Codonopsis* emits the most unpleasant smell, a mixture of *asafetida* and mangy fox.—N. G. HADDEN, *West Porlock, Somerset*.

THE ALPINE PANSY.

THE Alpine Pansy *par excellence* is *Viola calcarata*, surely the most variable of wildlings. Some of the forms are extraordinarily beautiful, and it is rather surprising that the plant is not more frequently found in gardens. One can find a hundred gardens which possess the Grecian *Viola*, *V. gracilis*, to every one which holds even one form of *V. calcarata*. Why is this? It cannot be because of any difficulty of culture or propagation, for it is as easily grown and increased as any of the race. Pure white, soft yellow, deep yellow, lavender and purple all are found in this species, which thus rivals the florists' *Violas* in range of colouring.—S. J. S.

[Perhaps our correspondent underrates the use

made in gardens of *V. calcarata*. So many forms of this species have been sent out as *Viola* "This," "That" or "The Other" that gardeners have become a little tired of all alpine *Violas* but the more distinct species. Readers who care to answer "S. J. S.'s" conundrum may like to explain, also, why our lovely native *V. lutea* is so little seen in gardens.—ED.]

A LOVELY CROCUS.

THAT beautiful mountain Crocus, *C. arius*, grows from 4,000ft. to 5,700ft. in Asia Minor and Kurdistan. Mr. Maw found it in quantity on Mount Olympus in 1877. In its native habitat it flowers in May, in cultivation in early February. It is nearly allied to *Crocus biflorus*, but can be easily distinguished by its red seed and rich purple blue flowers, which are shorter and broader than *C. biflorus*. A variety called *C. arius Celeste*, much paler blue, was sent me from Mr. T. Smith, Daisy Hill, Newry, in a pot, and later in the rock garden it has indeed been a fairy flower.—W. P. M.

FORTHCOMING EVENTS.

April 4.—Lewes Horticultural Society's Meeting.—Wimbledon Gardeners' Society's Meeting.

April 5.—Royal Horticultural Society of Ireland Spring Exhibition (two days).—Manchester and North of England Orchid Society's Meeting.—Jersey Gardeners' Society's Spring Exhibition.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Celery. Where seeds were sown a few weeks ago the young plants will soon be ready for pricking off in frames about 6 ins. apart. The frame should be placed on a hard base; a few inches of rotten manure laid in the bottom and covered with a layer of old potting soil or similar material. Make it fairly firm, and if at all dry give a thorough watering the day before the planting is done. Keep the lights close for a few days and shade the plants if necessary, but once they are re-established admit air freely, and finally dispense with the lights altogether. The seedlings must be hardened off before they are transferred to the cold frame.

Mushrooms.—Very few people dislike the Mushroom, and where it is possible to collect the necessary manure from the stables a bed should certainly be made. The droppings should be collected while fresh and with as little straw as possible. They should be stored in an open shed until the requisite quantity is obtained, when they should be turned over every second or third day until the rank fiery heat has escaped. Two or three cartloads will make a tolerably good bed, which should be about 4 ft. wide and 2 ft. or 3 ft. deep with a slope to the front. The manure must be trodden and beaten with the back of a spade to render it quite firm, and during the first few days the temperature will be high. This must be allowed to subside, and when the thermometer registers 80° or so the spawning should be done. The bricks of spawn should be broken into pieces about the size of a hen's egg and pushed in the manure at intervals of 5 ins. or 6 ins. The spawn should be only just covered with manure, and in a few days the bed given a thin layer of fine loam. A liberal sprinkling of clean straw will also help to keep the bed warm. An old shed or similar structure from which light is excluded will be ideal for Mushroom growing. Moisture is important, and when the bed is dry it should be sprinkled over with tepid water.

The Flower Garden.

Border Chrysanthemums.—Stock plants that have been stored in cold frames may be divided into small pieces and potted up or planted in the borders. Single shoots with roots attached may be potted off singly, and if more stock is required a batch of cuttings should be inserted. If sandy soil is used, the cuttings will readily form roots in a cold frame. For producing a quantity of cut flower in late autumn these Chrysanthemums are most valuable, and five or six good varieties should be grown.

The Rock Garden is now beginning to be most attractive, and where plants have failed they should be replaced. A few of the bare places could be filled with annuals, and the following are suitable: *Linum rubrum*, *Phacelia campanularia*, *Phlox Drummondii*, *Lobelia* and other dwarf-growing plants. It should, however, be borne in mind that annuals are only employed as a temporary effect until their stations can be filled with true alpine. The general work consists of keeping the rock garden free of weeds, preventing the more aggressive plants from overcrowding their choicer and smaller neighbours, and seeing that none suffers from drought during a spell of dry weather.

Fruit Under Glass.

Peaches and Nectarines. The late trees will have set their fruits, and these must be thinned at once. First of all remove deformed specimens and others where they are exceptionally thick. The young shoots will also require attention, but both disbudding and thinning of the fruit must be done gradually or the trees will receive a check. Admit air freely when the weather is favourable, and well spray the trees twice daily, closing the ventilators about three o'clock. The borders must be examined occasionally to ascertain the condition of the soil, because the surface may be wet from the damping down, but underneath the soil and roots may be dry. When such is the case a thorough soaking is the remedy. Keep a sharp watch for green and black fly on the young growths, as these pests do a lot of damage in a few days. If present, vapourise the house lightly or spray with a reliable insecticide.

Orchard-House. In this structure a miscellaneous collection of plants may be grown, and at this time most of the fruit will be set. During bright weather the trees should be syringed twice daily, first in the forenoon and again about three

o'clock when all the ventilators are closed. A moist, growing atmosphere is thus maintained, a little air being admitted in the morning before the sun raises the temperature excessively. Peaches will need disbudding, and a watch must be kept for grubs and caterpillars in leaves and shoots of Plums, etc. Pot trees will take a copious supply of water, and on no account ought they to become dry at the roots.

The Hardy Fruit Garden.

Wall Trees.—The soil around the base of these trees becomes more or less hard through the gardener treading on the ground when pruning, and it will be advisable to prick it over lightly with a fork. A mulching of manure may then be given. Should the weather prove dry, trees growing against walls will need a thorough watering. This is often overlooked, and much of the fruit fails to develop.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chesham, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Cauliflowers.—Autumn-sown Cauliflowers may now be planted out in all but the very cold districts. A ring of soot or sand placed round each plant will keep slugs at bay, a necessary precaution at this early date when food is scarce. Cauliflowers resulting from seed sown indoors in February should now be hardened off in a cold frame. Sow now in the open for succession. Early Erfurt or Early London, with Walcheren and Veitch's Autumn Giant, will keep up a succession till the end of the season.

Broccoli.—The variety Purple Sprouting will now be turning in, to be succeeded by the white varieties. Sow now for next season's crop. The following can be recommended for the various periods: Veitch's Autumn, Osborn's Winter, Veitch's Model and June Monarch or Methven's June. A sowing of Asparagus Kale (Buda Kale) should also be made for spring use.

Peas.—Continue to make fortnightly sowings of some maincrop variety. Where a 5 ft. variety is not objected to, The Gladstone can hardly be excelled. Of dwarf varieties Sharpe's Queen can be recommended. Sow Spinach between the rows.

Beet.—It is too early to sow the main crop, but a small sowing of a globe variety should be made for early use.

Cucumbers.—Regulate and tie the early batch, and pinch the laterals after the first joint beyond the fruit. Make a sowing for growing in frames on a slight hot-bed after the frames have been cleared of the bedding plants.

Vegetable Marrows.—Seed should be sown in moderate heat. Moore's Cream is a small variety of superior quality and Long White is a reliable large variety.

The Flower Garden.

Bedding Plants should now be transferred to cold frames, keeping the frames rather close for a week, after which the ventilation should be gradually increased according, of course, to climatic conditions.

Alyssum.—Such varieties as Little Dorrit or Sutton's Mimosa are indispensable for edgings, and now is the time to sow in a cool house. Sown in heat they become "drawn."

Pentstemons.—There are now many superior varieties in cultivation, hence their great popularity. The sooner they are planted out now the better. Whole beds, whole borders or drifts of them are more effective than single lines or small patches.

Gladioli. Dormant corms may now be planted with all safety. There is a great choice in these attractive autumn flowers. The primrose-section with its large-flowering hybrids is now very popular. Some of the large-flowering section are somewhat expensive for massing, but for this purpose there are such moderate-priced varieties as *branchleyensis*, *Hollandia*, the pink *branchleyensis*, *Ambera* (pink), *Braunstone* (light yellow) and *Childs* in mixture, a superior class. They may be planted in masses or planted in beds rather sparingly with a groundwork of something more dwarf.

Fruit Under Glass.

Melons. Where seeds were sown in February the resultant plants should now be fit for planting

out. A fairly heavy but fibrous loam suits the Melon best, and to this should be added about a fourth part of horse droppings plus a little bone-meal, also some old lime mortar if procurable. The compost should be left a week before being introduced to the melon-house. When placed in position it should be packed rather firm. Each plant should be planted on a slight mound or on a couple of turves placed grassy side down laid on top of the bed. These means are used as a preventive against canker at the neck, which often attacks the plants. Allow the soil three days to get warmed before planting. Maintain a temperature of 70° to 75°, which may be considerably exceeded with bright sunshine. See that sufficient atmospheric moisture is supplied by damping the pathway and syringing with tepid water when closing down the house. Sow now for succession in frames if a succession crop is desired. If it is intended to plant a second crop in the same house, sowing should be delayed for a few weeks.

Late Vines.—As the laterals extend tie them down by degrees, as they snap readily if bent too far at once. Stop the laterals after the second joint beyond the bunch. Stop sub-laterals beyond the first joint and do not allow more than one bunch to develop on any given shoot. The crop as a whole will probably have to be thinned out, the number of bunches to be retained depending upon their size. Where large bunches are to be used for exhibition purposes their number must be reduced to three or four at most.

The Orchard-House.—Unless early results are desired, very little fire-heat need be applied now. Attention must be given to thinning the young shoots and also the various fruits as they develop. Both operations should be carried out gradually so as not to give the trees any material check. Ventilate freely, but avoid draughts.

CHARLES COMFORT
(Formerly Head-gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Gerbera Jamesoni and the many beautiful hybrids are excellent for a supply of cut flower. They are easily raised from seed at this time, as they germinate readily in an intermediate temperature. In their younger stages they enjoy such a temperature, although as they increase in size they grow well in an ordinary greenhouse. They thrive best in a compost of light loam with a little leaf-soil and sand. For their size they require fairly large pots, 6 ins. being suitable. Generally speaking, they must be regarded as greenhouse plants, although in the South and West they do very well planted out in a warm border at the foot of a wall. They do best when planted out, and if there is a suitable position in a greenhouse they should be thus treated.

Campanula isophylla and its varieties alba and Mayii are very useful for the greenhouse during late summer and autumn; they all make excellent plants for medium-sized baskets. They are splendid window plants, and as such are generally grown by cottagers; in fact, the finest examples are usually seen in cottage windows. If not already done, they may be propagated at this time by means of cuttings, which root readily in a case in an ordinary greenhouse. During all stages of their cultivation these plants should be grown under perfectly cool conditions.

Campanula fragilis also makes a pretty basket plant for the cool greenhouse, and may be readily raised from seeds or cuttings.

Campanula garganica and its variety *hirsuta*, although they will succeed in the rock garden, are worth growing in large pans for the small unheated greenhouse. They grow freely in good medium loam with plenty of grit added, and are easily propagated by means of cuttings.

Amphicome Emodi.—This plant with its graceful foliage and beautiful rose and yellow flowers is excellent for a cold greenhouse. Like many other beautiful plants, I am afraid it is somewhat scarce in gardens at the present day. It may be increased by means of seed or cuttings, the latter rooting readily in a close case with slight bottom-heat, or even in a cold case, when the process is somewhat slower.

Amphicome arguta is a larger-growing and somewhat harder species. Although by no means such a choice plant as *A. Emodi*, it is worth a place in an unheated greenhouse. Both species grow well in a sandy loam with some leaf-soil and sand added.

Angelonia salicariaefolia and its variety alba are slender, graceful plants worth growing for the greenhouse. They are easily raised from seed

"Roses in December!" —in his garden.

In yours too—if you'll help your rose-bushes to grow hardy and robust. You can do it, as easily as he has, by using **ECLIPSE Fish Manure**. Your neighbours will crane their necks to take a look at *your* garden if you will learn this simple secret. It's the soil that's at fault nine times out of ten.

The soil isn't rich enough. Strengthen it with **ECLIPSE Fish Manure**—and you will get hardy plants and rich deep coloured blooms, in season and out of season.

Eclipse Fish Manure contains Phosphates, Nitrogen and Potash in their proper proportions. Being largely organic, it supplies humus to the soil.

at this time. As these plants are slender, growing they should be stopped once to cause them to break, or three plants may be grown in a pot. If good specimens are required, they should be potted on into 6in. pots, although useful plants can be grown in 48-sized pots. These plants grow quite well in any ordinary potting compost, and may also be propagated by means of cuttings.

Anomatheca cruenta.—This pretty little South African bulbous plant, although fairly hardy in warm borders at the foot of a wall, is well worth growing in pots or pans for a cold house. It increases very quickly and about this time the plants may be turned out of their pots, divided up and repotted. It grows freely in sandy loam with some leaf-soil added to the compost. The plants may be grown in a cold frame until they reach the flowering stage, when they should be removed to the house. They ripen plenty of seeds, which germinate freely and thus afford a ready means of increase. There is also a very pretty white variety.

Blandfordia is a beautiful genus of Australian plants which I am afraid are poorly represented in gardens at the present day, with the possible exception of *B. nobilis*. They are by no means easy plants to grow successfully, although only requiring ordinary greenhouse treatment. They should be potted in a compost consisting of equal parts good medium loam and fibrous peat, with some coarse clean sand added. After repotting the plants should be very carefully watered until they become established. During the winter they should be kept on the dry side. They may be propagated by division or from seed.

Cantua buxifolia (syn. *B. dependens*) is a very beautiful greenhouse climber, well adapted for training to a rafter or wires under the roof glass. In the West of England this plant succeeds in sheltered position in the open. The plant is very subject to attacks by red spider, which may be prevented by a free use of the syringe. It is easily propagated by means of cuttings under a bell-glass in a cool house, the plants growing well in a good medium loam with leaf-soil and sand added. The sites where they are planted out should be well drained.

Royal Botanic Gardens, Kew. J. COULTS.

A Pretty Woodland Plant.—For a cool corner in well drained loam the little Japanese *Tanaka radicans* is delightful. From its rather sparse tuft of leaves, which are dark green and leathery, and large for so small a plant, it sends up in full summer 4in. to 6in. stems, each of which breaks into a spray of white flowers like that of some diminutive *Spiraea*. *T. radicans* spreads by means of underground runners, and where it is thoroughly satisfied with the conditions will soon cover a considerable space. This, however, is one of those plants which are more apt to sulk than to die. Though not difficult, it appears to be exacting in regard to situation. By moving it about one can generally manage to hit upon a place that will give it what it needs, and it is well worth the trouble.

Loganberries are not nearly so much grown by the amateur as their merits deserve, for they are excellent for cooking and preserving. Moreover, they are in season when small fruits are more or less scarce. The shoots will grow to a good height, so, to secure the best results, fairly high supports are needed, and nothing is better than a few stout poles with wires at intervals of 2ft. or 3ft. The pruning should be done after the fruit is gathered, but often it is left till this time. This pruning consists of cutting out the old growths and replacing them with new shoots, of which there are usually ample. There are a number of these berries in commerce, while the Blackberries ought not to be overlooked where there is space to grow them.

Dipelta floribunda.—This is one of the newer Chinese shrubs, and it is still somewhat rare in our gardens. It is a deciduous species, making a bush up to 5ft. or 6ft. in height and probably more in favourable situations. It has proved a good and easy doer in a warm loam and seems perfectly hardy. In leafage and habit it bears

some resemblance to a *Philadelphus*, but the flowers, produced in early summer, are tubular, nearly 1½in. long and about ½in. wide at the prettily lobed mouth. In colour they are a clear bluish or pale rose, with an orange throat. They are freely produced at the leaf-axils and very fragrant. There is little doubt that *D. floribunda* is a fine lover.

Hybrid Mimuluses. For culture indoors one or two hints will suffice to put cultivators on the high road to success. Whether stock is raised from seed or cuttings, cool culture from the start is by far the best. During the young stages, while greenhouse or frame protection is necessary, it should be contrived by some means to keep the plants well up, as close as possible to the glass. Thus a short stocky growth will be ensured. For potting, a compost consisting of fibrous loam, sharp sand and a little of either well seasoned cow manure or sheep manure will suit admirably, and the plants should be potted on to 48-sized pots before the smaller sizes are quite filled with roots. As soon as the first buds appear liquid manure may be given, adopting the good old plan of giving the stimulant weak and often rather than attempting high strength. Always allow free circulation of air, and from the time the first blossoms fall continually pick over to remove seed-pods and stems that are becoming exhausted. By these methods plants have been had continuously in bloom from early May to the end of September and even into October. Last year, in fact, some of the same plants were shewn at the Holland Park Rink Show as were staged at Chelsea.

Styrax Hemsleyana.—To connoisseurs of hardy trees and shrubs, the genus *Styrax* is already known by two Japanese species of remarkable beauty—*S. japonica* and *S. Obassia*. To the latter, *S. Hemsleyana*, a new species brought from China about fifteen years ago, bears most resemblance. Messrs. Veitch shewed a small tree at the International Exhibition at Chelsea in 1912. Its pure white flowers are about 1 inch wide, and its racemes are 6 inches or so in length; its leaves are 3 inches to 6 inches long, and about two-thirds as wide. It is a small deciduous tree which Mr. Wilson said he saw in China sometimes 20 feet or a little more in height. The *Styraxes* like to be given a permanent spot early, for they do not relish root disturbance. At the time of planting they may have a little prepared compost of peat and leaf-soil mixed with the soil put about their roots for them to start into; after they are established the roots can spread into the ordinary soil of the garden. Shrubs of such exquisite beauty as these deserve a little initial care. Probably the finest plant in this country is in Mr. J. C. Williams' garden at Caerhays, in Cornwall. It is about 12 feet high.

The Midland Daffodil Show.—We understand that this famous show will this year take place at the Botanic Gardens, Edgbaston, Birmingham, on Wednesday and Thursday, April 18 and 19, when a good display is anticipated.

R.H.S. Daffodil Show.—Readers are reminded that there is this season a Daffodil Show run entirely by the Royal Horticultural Society's Daffodil Committee, which, in fact, amounts to much the same thing, from a practical point of view, as a National Society. The schedule is a very good one, and there are classes suitable for the amateur with a small collection. The closing date for entries is April 7, and the Show is on Thursday and Friday, April 12 and 13, 1923. Schedules may be obtained from the Hon. Secretary to the Daffodil Show Committee, Mr. Herbert Smith, Fenby Street, Birmingham. Everyone interested in Daffodils should make a point of supporting the show by staging an exhibit.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

SOME SUITABLE PLANTS FOR A NORTH BORDER ("Lark").—*Violas* should do well in the north aspect; also herbaceous *Anemones*, Foxgloves, Solomon's Seal, *Aquilegia*, Saxifrage, Pansies, Mignonette, Fuchsias and early-flowering *Chrysanthemums*. Raise a stock of Primroses and Polyanthus now in readiness for autumn planting and Narcissi. Be careful to avoid overcrowding of the plants and so secure more sturdiness of each specimen. Only a small quantity of well rotted manure will be needed. To fill gaps plant a few *Asters* and Stocks.

FOLIAGE PLANTS FOR WARM, DRY BEDS (L. M. S.).—A few of each of the following kinds of foliage plants would be suitable for association with flowers in the garden, namely, *Cannas*, green and dark leaved; *Ricinus* Gibsoni (Castor Oil Plant); *Nicotiana glauca* (Tobacco), white, fragrant flowers, too; and *Centaurea* for the outer parts of the beds. The berry to which our correspondent refers is, undoubtedly, the Lowberry, the result of a cross between the Loganberry and the Blackberry. The growth is similar to that of the Loganberry, and there is no hard core; it is darker in the fruits than the Loganberry and has the flavour of the Blackberry.

RENEWING SOIL FOR GLADIOLI (G. H., Surrey).—It is always best to prepare the soil for the corns in the autumn. As this cannot be done in our correspondent's case, the manure used must be well rotted. Of the decayed vegetable refuse from the old marrow-bed use liberally, of leaf-mould moderately; no fresh cow or donkey manure, but a small quantity of the older cow droppings. Do not use freshly slacked lime, but about 1lb. of old exposed lime or 2lb. of lime rubble per square yard will not be injurious to them, nor to *Hyacinthus-candicans*. If the soil is clayey or inclined to be heavy in nature, add wood ashes freely—a 6in. potful per square yard. Also add any gritty material and a handful of dry, coarse sand round each corn at planting-time. In all cases the wood ashes are beneficial.

THE GREENHOUSE.

TREATMENT OF INDIAN AZALEAS (E. S.).—The method of culture followed seems to be quite correct. The aim should be to encourage the plants to make plenty of new growths, as it is these which produce the flowers the next year. Sometimes plants flower profusely in alternate years, using the intervening years to make new growths. Perhaps our correspondent's plants flowered well last year. If the plants do not make good growth, they may need repotting, not necessarily into larger pots, but a fresh compost of peat, leaf-mould, coarse sand and lime-free loam should be used if available.

MISCELLANEOUS.

HOW TO DISPOSE OF OLD TINS, CINDERS AND ASHES (J. W. W.).—A hole of moderate size will contain many tins if these are first flattened, and bottles if they are broken up. All such refuse should be buried quite 18in. below the surface. The ashes will certainly prove useful on the garden paths. It is always wise on the part of the owner of a garden to have, in an out of the way corner, a fire occasionally to reduce to ashes weeds, old stacks and rubbish generally, as the ashes are beneficial to the crops if returned in that form to the soil, and the cinders will help in the burning of the refuse.

VARIOUS QUESTIONS (I. W., Edinburgh).—Possibly, late planting followed by the flowering of the bulbs may account for the subsequent weakening and non-flowering of the *Narcissi* bulbs the second year. Early planting—in September if possible—and allowing the bulbs to remain in the soil for three years should be the course followed; the foliage must not be removed till it has browned and matured. A judicious shortening of the lower leaves of the *Tritomas* will not prove harmful. Crown Imperials ought to thrive well in Edinburgh. They should be planted in a fairly moist soil in the autumn. The plants are hardy, but if frosts damage them insert a few green boughs, such as fir branches, among them. Perhaps the roots of the Holly bush rob those of the Glory of the Highlands (if *Tropeolum speciosum* is referred to) too much. The plant thrives best in a north aspect and does well when established. We advise trying a fresh position and to protect the roots from frost.

NAMES OF PLANTS.—M. B. J., Somerset.—*Rhododendron Christnae*—Cheer.—C. B. K., Reading.—*Cornus capitata*.
